N94-19800 to N94-22701

The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON, and through DIALOG as the Aerospace Database.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **1635**

02 AERODYNAMICS **1636**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **1641**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **1642**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **1645**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **1647**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **1647**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **1650**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **1650**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **1652**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **1652**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **1653**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **1653**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **1653**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **1656**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **1657**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **1666**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **1666**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **1672**

24 COMPOSITE MATERIALS **1672**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **1678**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **1687**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **1697**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **1711**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **1713**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **1713**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **1715**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **1748**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **1796**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **1806**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **1814**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **1821**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **1828**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **1828**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **1836**

43 EARTH RESOURCES AND REMOTE SENSING **1837**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **1844**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **1850**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **1854**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **1864**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **1881**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **1884**

52 AEROSPACE MEDICINE **1889**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **1893**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **1895**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY **1897**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **1897**

60 COMPUTER OPERATIONS AND HARDWARE **1898**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **1902**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **1928**
Includes computer networks and special application computer systems.

63 CYBERNETICS **1938**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **1949**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **1962**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **1965**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **1965**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **1966**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **1967**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **1969**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **1979**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **1983**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **1991**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **2011**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **2037**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **2038**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **2039**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **2041**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **2049**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY ..... **N.A.**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **2053**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) ..... **N.A.**

89 ASTRONOMY **2054**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **2080**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **2088**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **2147**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **2149**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

SOME VTOL HEAD-UP DISPLAY DRIVE-LAW PROBLEMS AND SOLUTIONS

Vernon K. Merrick Nov. 1993 45 p

(RTOP 533-02-37)

(NASA-TM-104027; A-93090; NAS 1.15:104027) Avail: CASI HC A03/MF A01

A piloted simulation test was conducted on the Ames Research Center's vertical motion simulator (VMS) in support of the Phase 2A flight test of NASA's V/STOL systems research aircraft (VSRA). During the simulation several problems were found with the head-up display (HUD) symbol drive laws and the flightpath synthesis. These problems and the solutions devised to solve them are described. Most of the resulting HUD drive-law changes were implemented during the simulation and their effectiveness was verified. Subsequently both the HUD symbol drive-law and flightpath-synthesis changes were implemented in the VSRA and tested successfully in the Phase 2A flight tests. Author (revised)

AIAA TECHFEST 29 PROCEEDINGS

William H. Wentz, Jr., ed. and Jacqueline R. Luedtke, ed. 1993 217 p Conference held in Wichita, KS, 6-7 Nov. 1992

(NIAR-93-1) Avail: CASI HC A10/MF A03

Proceedings for the nineteenth annual techfest are accompanied by visual displays for selected topics. Selected topics in structures include limit-cycle oscillations of aircraft lifting surfaces; automated airframe monitoring; low-cost, high-performance target drone wing manufacturing process comparison; and elevated temperature testing considerations for various material systems. Experimental methods and instrumentation that were discussed included low-cost piloted flight simulation, and overview of doppler global velocimetry, and overview of the NIAR crash-dynamics lab, modernization of the Walter Beech Wind Tunnel, development of a PC-based real-time PCM display and analysis system. Topics in aerodynamics include axial flow fan research underway at the University of Kansas, axial agility and pitch agility of fighter aircraft revisited, an experimental and numerical investigation of a 70 degree delta wing at high angles of attack, and the adaptation of ACSYNT for business jet configuration synthesis. CASI

AERONAUTICAL ENGINEERING: A CONTINUING BIBLIOGRAPHY WITH INDEXES (SUPPLEMENT 294)

Aug. 1993 167 p

(NASA-SP-7037(294); NAS 1.21:7037(294)) Avail: CASI HC A08

This issue of Aeronautical Engineering - A Continuing Bibliography with Indexes lists 590 reports, journal articles, and other documents recently announced in the NASA STI Database. The coverage includes documents on the engineering and theoretical aspect of design, construction, evaluation, testing, operation, and performance of aircraft (including aircraft engines) and associated components, equipment, and systems. It also includes research and development in aerodynamics, aeronautics, and ground support equipment for aeronautical vehicles. The bibliographic series is compiled through the cooperative efforts of the American Institute of Aeronautics and Astronautics (AIAA) and the National Aeronautics and Space Administration (NASA). Seven indexes are included: subject, personal author, corporate source, foreign technology, contract number, report number, and accession number. Derived from text

THE MODERN ROTOR AERODYNAMIC LIMITS SURVEY: A REPORT AND DATA SURVEY

J. Cross, J. Brilla, R. Kufeld, and D. Balough Oct. 1993 261 p

(RTOP 505-59-36)

(NASA-TM-4446; A-91183; NAS 1.15:4446) Avail: CASI HC A12/MF A03

The first phase of the Modern Technology Rotor Program, the Modern Rotor Aerodynamic Limits Survey, was a flight test conducted by the United States Army Aviation Engineering Flight Activity for NASA Ames Research Center. The test was performed using a United States Army UH-60A Black Hawk aircraft and the United States Air Force HH-60A Night Hawk instrumented main-rotor blade. The primary purpose of this test was to gather high-speed, steady-state, and maneuvering data suitable for correlation purposes with analytical prediction tools. All aspects of the data base, flight-test instrumentation, and test procedures are presented

and analyzed. Because of the high volume of data, only select data points are presented. However, access to the entire data set is available upon request. Author (revised)

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

EXPERIMENTAL STUDY ON INTERFERENCE AERODYNAMICS OF CLOSE-COUPLED CANARD CONFIGURATION

Yao-Bin Guo 20 Jul. 1993 19 p Transl. into ENGLISH from Hangkong Xuebao (China), v. 11, no. 12, 1990 p 528-533

(AD-A267760; FASTC-ID(RS)T-0730-92) Avail: CASI HC A03/MF A01

By using the canard-wing balance and the whole aircraft aerodynamic balance, which can measure the aerodynamic forces of the canard-wing part, experimental studies were conducted on interference aerodynamic forces on a canard-configuration model that can be assembled and disassembled. It was discovered that the interferences are destructive between the canard wing and the main wing when alpha is less than 20 deg, causing a reduction in the lift. When alpha is greater than 32 deg, the interferences turn increasingly beneficial. When alpha = 32 deg, the interference lift increases to 24 percent of total lift. If the main wing is a swept-forward wing, the aerodynamic properties of the canard configuration are better. Author

EXPERIMENTAL INVESTIGATION OF NOZZLE/PLUME AERODYNAMICS AT HYPERSONIC SPEEDS Progress Research Report, 1 Dec. 1992 - 30 Jun. 1993

David W. Bogdanoff and Jean-Luc Cambier 30 Jun. 1993 32 p

(Contract NCC2-487)

(NASA-CR-194628; NAS 1.26:194628) Avail: CASI HC A03/MF A01

Work continued on the improvement of 16-Inch Shock Tunnel. This comprised studies of ways of improving driver gas ignition, an improved driver gas mixing system, an axial translation system for the driver tube, improved diaphragm materials (carbon steel vs. stainless steel), a copper liner for the part of the driven tube near the nozzle, the use of a buffer gas between the driver and driven gases, the use of N2O in the driven tube, the use of a converging driven tube, operation of the facility as a non-reflected shock tunnel and expansion tube, operation with heated hydrogen or helium driver gas, the use of detonations in the driver and the construction of an enlarged test section. Maintenance and developmental work continued on the scramjet combustor continued. New software which greatly speeds up data analysis has been written and brought on line. In particular, software which provides very rapid generation of model surface heat flux profiles has been brought on line. A considerable amount of theoretical work was performed in connection with upgrading the 16 Inch Shock Tunnel Facility. A one-dimensional Godunov code for very high velocities and any equation of state is intended to add viscous effects in studying the operation of the Shock Tunnel and also of two-stage light gas guns. Derived from text

THE FLUID MECHANICS OF VORTEX CUTTING BY A BLADE Final Report, 1 Aug. 1992 - 31 Jul. 1993

Jeffrey S. Marshall 25 Sep. 1993 31 p

(Contract DAAL03-92-G-0277)

(AD-A270932; ARO-30168.5-EG-YIP) Avail: CASI HC A03/MF A01

A study of the nonlinear response of a vortex to the approach of, and cutting by, a blade traveling in the plane normal to the vortex axis has been performed. Two different types of vortex forces on the blade are distinguished. For large values of the ratio of blade thickness T to vortex ambient core radius sigma(0), the force on the blade is primarily due to decreased pressure near the blade leading edge due to bending of the vortex about the blade. For values of T/sigma(0) of 0(1) or less, the vortex does not bend substantially during interaction with the blade and instead the blade passes through, or 'cuts', the vortex. In this case, the force on the blade is primarily due to formation of a vortex shock which propagates on the vortex away from the blade, and the subsequent difference in vortex core radius on opposite sides of the blade due to the vortex shock. This study was conducted based on analytical, computational and experimental studies, the results of which compared well in the regimes in which each are valid. DTIC

EXPERIMENTAL AND COMPUTATIONAL RESULTS FROM A LARGE LOW-SPEED CENTRIFUGAL IMPELLER

M. D. Hathaway (Army Research Lab., Cleveland, OH.), R. M. Chriss, J. R. Wood, and A. J. Strazisar Dec. 1993 12 p Presented at the 82nd Meeting of the AGARD Propulsion and Energetics Panel, Technology Requirements for Small Gas Turbine Engines, Montreal, Ontario, 4-6 October, 1993; sponsored by the Advisory Group for Aerospace Research and Development

(DA Proj. 1L1-61102-AH-45)

(NASA-TM-106421; E-8258; NAS 1.15:106421; ARL-TR-331) Avail: CASI HC A03/MF A01

An experimental and computational investigation of the NASA Low-Speed Centrifugal Compressor (LSCC) flow field has been conducted using laser anemometry and Dawes' 3D viscous code. The experimental configuration consists of a backswept impeller followed by a vaneless diffuser. Measurements of the three-dimensional velocity field were acquired at several measurement planes through the compressor. The measurements describe both the throughflow and secondary velocity field along each measurement plane and in several cases provide details of the flow within the blade boundary layers. The experimental and computational results provide a clear understanding of the development of the throughflow momentum wake which is characteristic of centrifugal compressors. Author

The objective of this research was to identify the principal cause and effect relationships in dynamic stall at large Reynolds numbers, as well as possible means for controlling the process. At high Reynolds numbers, it is demonstrated the formation of the dynamic stall vortex initiates for all airfoil shapes via an unsteady separation of the boundary layer near the leading edge. The stall vortex ultimately detaches from the upper surface by provoking an unsteady separation of the surface layer near midchord. At least two methods of controlling separation at various stages in the cycle have been identified, namely: (1) suction near the leading nose or at midchord; and (2) a moving portion of the surface. The present work shows how separation can be suppressed and makes significant contributions to the theory of unsteady boundary-layer separation. A general analysis of unsteady two-dimensional airfoil maneuvers was initiated and is currently under study as a possible third means of control. DTIC

(AD-A270201; Paper-C18) Avail: CASI HC A03

The present paper describes an experiment in which laser velocimetric methods are employed to investigate the drag mechanisms of a helicopter rotor in hover. Emphasis is on the development of a measurement technique capable of quantifying, the contribution of rotor profile drag to total power

required. The scheme devised employs a 2-D LV system to measure the axial and tangential velocity field in the vicinity of the rotor blade. Application of a combined Kutta and Momentum Equation (KME) along a closed contour surrounding the blade section provides a measure of the local sectional normal and shear forces. A detailed survey of the rotor blade's near wake region is then performed in an attempt to directly determine the streamwise, velocity deficit. Integration of the resulting velocity profiles provides a measure of the profile drag. Accuracy of the method is checked by performing measurements at conditions of very low lift and by introducing blade surface modifications which aggravate the profile drag with accompanying comparisons of the effect on sectional and global performance. (NASA-TM-106399; E-8231; NAS 1.15:106399; AIAA Paper 93-2964)

Avail: CASI HC A03/MF A01

New turbulence modeling options recently implemented for the 3-D version of Proteus, a Reynolds-averaged compressible Navier-Stokes code, are described. The implemented turbulence models include: the Baldwin-Lomax algebraic model, the Baldwin-Barth one-equation model, the Chien k-epsilon model, and the Launder-Sharma k-epsilon model. Features of this turbulence modeling package include: well documented and easy to use turbulence modeling options, uniform integration of turbulence models from different classes, automatic initialization of turbulence variables for calculations using one- or two-equation turbulence models, multiple solid boundaries treatment, and fully vectorized L-U solver for one- and two-equation models. Validation test cases include the incompressible and compressible flat plate turbulent boundary layers, turbulent developing S-duct flow, and glancing shock wave/turbulent boundary layer interaction. Good agreement is obtained between the computational results and experimental data. Sensitivity of the compressible turbulent solutions with the method of y(sup +) computation, the turbulent length scale correction, and some compressibility corrections are examined in detail. The test cases show that the highly optimized one-and two-equation turbulence models can be used in routine 3-D Navier-Stokes computations with no significant increase in CPU time as compared with the Baldwin-Lomax algebraic model.

DEVELOPMENT OF PHASED TWIN FLIP-FLOP JETS

Ganesh Raman (Sverdrup Technology, Inc., Brook Park, OH.) and Edward J. Rice Nov. 1993 10 p Proposed for presentation at the ASME Winter Annual Meeting, New Orleans, LA, 28 Nov. - 3 Dec. 1993; sponsored by ASME

(Contract NAS3-25266; RTOP 505-62-52)

(NASA-TM-106404; E-7609; NAS 1.15:106404) Avail: CASI HC A02/MF A01

The flip-flop nozzle is a device that can produce an oscillating jet flow without any moving parts. There is now a renewed interest in such nozzles due to their potential for use as excitation devices in practical applications. An experiment aimed at developing twin flip-flop jets that operate at prescribed frequencies and phase differences was performed. The phasing was achieved using two different nozzle interconnection schemes. In one configuration the two jets flapped in-phase and in another they flapped out-of-phase with respect to each other. In either configuration the frequencies of oscillation of both jets were equal. When one of the jets was run at a constant high velocity and the velocity of the second jet was increased gradually, the higher velocity jet determined the frequency of oscillation of both jets. The two flip-flop jet configurations described could be used to excite a primary jet flow in either an anti-symmetric (sinuous) or a symmetric (varicose) mode. Author (revised)

PREDICTION AND CONTROL OF VORTEX-DOMINATED AND VORTEX-WAKE FLOWS Progress Report, 1 Dec. 1992 - 30 Nov. 1993

Osama Kandil Dec. 1993 123 p

(Grant NAG1-994)

(NASA-CR-194722; NAS 1.26:194722) Avail: CASI HC A06/MF A02

This progress report documents the accomplishments achieved in the period from December 1, 1992 until November 30, 1993. These accomplishments include publications, national and international presentations, NASA presentations, and the research group supported under this grant. Topics covered by documents incorporated into this progress report include: active control of asymmetric conical flow using spinning and rotary oscillation; supersonic vortex breakdown over a delta wing in transonic flow; shock-vortex interaction over a 65-degree delta wing in transonic flow; three dimensional supersonic vortex breakdown; numerical simulation and physical aspects of supersonic vortex breakdown; and prediction of asymmetric vortical flows around slender bodies using Navier-Stokes equations. AN EFFICIENT NUMERICAL METHOD FOR THREE-DIMENSIONAL HYPERSONIC FLOW Final Report, 15 Jan. 1987 - 15 Nov. 1992

Robert W. MacCormack Feb. 1993 40 p

(Contract F33615-86-C-3015; AF Proj. 2307)

(AD-A272506; WL-TR-93-3012) Avail: CASI HC A03/MF A01

The present paper presents an efficient algorithm for solving the unsteady Navier-Stokes equations. It is a line Gauss-Seidel relaxation implicit algorithm for three-dimensional flow. Such algorithms have shown very fast convergence properties for two-dimensional flow. The extension to three-dimensions has been troublesome. The proposed algorithm presented herein was developed to solve these difficulties. A computer program based upon this algorithm has been written to solve two-dimensional plane symmetric, axisymmetric or three-dimensional flow of a perfect gas, or a real gas model for air with five species (N2, 02, NO, N, 0) or seven species (N2, 02, NO, NO+, N, 0, e-). The program can simulate a gas in thermal equilibrium or in thermal nonequilibrium with two temperatures (Translational-Rotational and Vibrational) or three temperatures (Translational, Rotational, and Vibrational). Convergence to engineering accuracy is generally achieved in under a hundred time steps for both two- and three-dimensional flow. Provision is made within the program for a one or two equation turbulence model. Applications are presented to verify the code by comparison with experiment and flight tests. Finally, the numerically simulated flow about a hypersonic vehicle at Mach 25 in powered flight is presented. DTIC

INTERNAL PERFORMANCE OF A NONAXISYMMETRIC NOZZLE WITH A ROTATING UPPER FLAP AND A CENTER-PIVOTED LOWER FLAP

David J. Wing, Laurence D. Leavitt, and Richard J. Re Nov. 1993 59 p

(RTOP 505-62-30-01)

(NASA-TP-3385; L-17235; NAS 1.60:3385) Avail: CASI HC A04/MF A01

An investigation was conducted at wind-off conditions in the static-test facility of the Langley 16-Foot Transonic Tunnel to determine the internal performance characteristics of a single expansion-ramp nozzle with thrust-vectoring capability to 105 degrees. Thrust vectoring was accomplished by the downward rotation of an upper flap with adaptive capability for internal contouring and a corresponding rotation of a center-pivoted lower flap. The static internal performance of configurations with pitch thrust-vector angles of 0 degrees, 60 degrees, and 105 degrees each with two throat areas, was investigated. The nozzle pressure ratio was varied from 1.5 to approximately 8.0 (5.0 for the maximum throat area configurations). Results of this study indicated that the nozzle configuration of the present investigation, when vectored, provided excellent flow-turning capability with relatively high levels of internal performance. In all cases, the thrust vector angle was a function of the nozzle pressure ratio. This result is expected because the flow is bounded by a single expansion surface on both vectored- and unvectored-nozzle geometries. Author

A STUDY OF THE COMPRESSIBLE FLOW THROUGH A DIFFUSING S-DUCT

Steven R. Wellborn (Iowa State Univ. of Science and Technology, Ames.), Theodore H. Okiishi (Iowa State Univ. of Science and Technology, Ames.), and Bruce A. Reichert Dec. 1993 108 p Sponsored by NASA. Washington

(RTOP 505-62-52)

(NASA-TM-106411; E-8247; NAS 1.15:106411) Avail: CASI HC A06/MF A02

Benchmark aerodynamic data are presented for compressible flow through a representative S-duct configuration. A numerical prediction of the S-duct flow field, obtained from a subsonic parabolized Navier-Stokes algorithm, is also shown. The experimental and numerical results are compared. Measurements of the three-dimensional velocity field, total pressures, and static pressures were obtained at five cross-sectional planes. Aerodynamic data were gathered with calibrated pneumatic probes. Surface static pressure and surface flow visualization data were also acquired. All reported tests were conducted with an inlet centerline Mach number of 0.6. The Reynolds number, based on the inlet centerline velocity and duct inlet diameter, was 2.6 x 10(exp 6). Thin inlet turbulent boundary layers existed. The collected data should be beneficial to aircraft inlet designers and the measurements are suitable for the validation of computational codes. The results show that a region of streamwise flow separation occurred within the duct. Details about the separated flow region, including mechanisms which drive this complicated flow phenomenon, are discussed. Results also indicate that the duct curvature induces strong pressure driven secondary flows. The cross flows evolve into counter-rotating vortices. These vortices convect low momentum fluid of the boundary layer toward the center of the duct, degrading both the uniformity and magnitude of the total pressure profile. Author

CONCEPT REPORT: EXPERIMENTAL VECTOR MAGNETOGRAPH (EXVM) OPERATIONAL CONFIGURATION BALLOON FLIGHT ASSEMBLY Final Report

Dec. 1993 57 p

(Contract NAS8-38089; NASA Order H-07978-D)

(NASA-CR-194702; NAS 1.26:194702) Avail: CASI HC A04/MF A01

The observational limitations of earth bound solar studies has prompted a great deal of interest in recent months in being able to gain new scientific perspectives through, what should prove to be, relatively low cost flight of the magnetograph system. The ground work done by TBE for the solar balloon missions (originally planned for SOUP and GRID) as well as the rather advanced state of assembly of the EXVM has allowed the quick formulation of a mission concept for the 30 cm system currently being assembled. The flight system operational configuration will be discussed as it is proposed for short duration flight (on the order of one day) over the continental United States. Balloon hardware design requirements used in formulation of the concept are those set by the National Science Balloon Facility (NSBF), the support agency under NASA contract for flight services. The concept assumes that the flight hardware assembly would come together from three development sources: the scientific investigator package, the integration contractor package, and the NSBF support system. The majority of these three separate packages can be independently developed; however, the computer control interfaces and telemetry links would require extensive preplanning and coordination. A special section of this study deals with definition of a dedicated telemetry link to be provided by the integration contractor for video image data for pointing system performance verification. In this study the approach has been to capitalize to the maximum extent possible on existing hardware and system design. This is the most prudent step that can be taken to reduce eventual program cost for long duration flights. By fielding the existing EXVM as quickly as possible, experience could be gained from several short duration flight tests before it became necessary to commit to major upgrades for long duration flights of this system or of the larger 60 cm version being considered for eventual development. NONLINEAR AERODYNAMICS AND THE DESIGN OF WING TIPS Final Report, 1 Apr. 1992 - 31 Mar. 1993

Ilan Kroo and Sean Wakayama Sep. 1993 14 p

(Contract NCC2-683)

(NASA-CR-194732; NAS 1.26:194732) Avail: CASI HC A03/MF A01

This contract began in April 1990 with studies on the effect of wingtip shape on induced drag. That work considered problems of determining induced drag from computational aerodynamic methods and examined effects of wake roll up on the induced drag of elliptical and crescent wings. The research contract was continued in April 1991 and again in April 1992 with scope augmented to include considerations other than induced drag. The idea was to develop methods for comparing wing tip shapes on the basis of their effects on total drag, structural weight, and high lift performance. To accomplish this, work was done to improve methods for multidisciplinary analysis and optimization of wings. This report describes results of research conducted from April 1992 through March 1993. The general objective was to improve an existing wing optimization method and apply the method to specific problems of interest. The method, while a valuable tool for wing tip design studies, can be applied to more general problems, and has been applied to some of these other problems during its development. Specific goals that were accomplished are listed below and are explained in more detail in attached reports: analysis methods were improved in the area of structural modeling; small improvements to the high lift model were made, and ideas were collected on how clean wing c(sub l(sub max)) should vary with sweep - these ideas should provide a guide for future examination of high lift with experiment or CFD; and a calculation for drag due to the loss of leading edge suction was added to the wing analysis. NEAR WAKE MEASUREMENTS ON A ROTOR MODEL WITH MIE-VANES IN THE DELFT OPEN JET TUNNEL

H. Imamura and N. J. Vermeer Aug. 1992 33 p See also PB92-202845 Prepared in cooperation with Mie Univ.

(PB93-215382; IW-92052R) Avail: CASI HC A03/MF A01

As a part of the international collaboration between Mie University and Delft University of Technology, near wake measurements behind a rotor model with Mie-vanes have been performed in the Delft open jet wind tunnel. Preceding these measurements, the performance measurements of this rotor model with Mie-vanes have already been carried out in Delft. In these measurements, the augmentation of rotor output power by application of Mie-vanes was not obtained. This can partly be contributed to higher optimal tip speed ratio of the Delft rotor model. INSTABILITY MODES EXCITED BY NATURAL SCREECH TONES IN A SUPERSONIC RECTANGULAR JET

Ganesh Raman (Sverdrup Technology, Inc., Brook Park, OH.) and Edward J. Rice Dec. 1993 18 p Presented at the 15th AIAA Aeroacoustics Conference, Long Beach, CA, 25-27 Oct. 1993; sponsored by AIAA

(RTOP 505-62-52)

(NASA-TM-106409; E-8246; NAS 1.15:106409; AIAA Paper 93-4321)

Avail: CASI HC A03/MF A01

The evolution of hydrodynamic instability modes self-excited by harmonically related natural screech tones was experimentally investigated. A convergent rectangular nozzle with an aspect ratio of 9.63 was used to produce a supersonic shock containing jet. Measurements in the flow-field were made using standard hot-film probes positioned only in the subsonic (outer) portions of the flow. The hydrodynamic instability mode observed in the shear layer at the screech frequency was observed to be antisymmetric (sinuous) about the smaller dimension of the jet, whereas its harmonic was observed to be symmetric (varicose). In addition, the near-field noise measurements indicated that the radiated screech tone noise was out of phase on either side of the small jet dimension whereas its harmonic was in phase over the same region. To our knowledge such an observation on the nature of the harmonic has thus far gone unreported and therefore is the focus of the present work. The hydrodynamic instability modes occurring at the screech frequency and its harmonic satisfied the conditions for

resonance. Detailed measurements of the coherent wave evolution in the streamwise and spanwise directions indicated that strong spanwise variations were present beyond x/h = 8. Details of the screech noise radiated by the coherent instability modes are also presented in this paper.

New applications of the wake source model, a two-dimensional incompressible potential flow model used for bodies experiencing flow separation, are presented. The body contour is conformally mapped to a circle, for which the problem is solved using source singularities to create free streamlines simulating the separating shear layers. In common with other inviscid theories, it generally requires the pressure in the separated flow region, and the location of separation if boundary layer controlled. Different mapping sequences and flow models have been constructed for the cases of trailing-edge stall for single element airfoils, flat plates with separation bubbles, separation bubbles upstream of spoilers with downstream wakes, spoiler/slotted flap combinations at which the spoiler inclination is arbitrary, and two-element airfoils near stall. Predictions of pressure distribution are compared with wind tunnel measurements, good agreement is found in the 1st and 5th cases, and results in the 2nd and 3rd cases are promising. Partial success was achieved for the 4th case, depending on spoiler inclination; the discrepancy diminishes as the spoiler angle decreases in the cases of higher incidences so that the wake boundary tugs away from the flap sooner. TRANSONIC FLOW CALCULATIONS: INTEGRAL METHOD M.S. Thesis
Marc Langlois 1993 110 p
(ISBN-0-315-83538-9; CTN-94-60948) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

An integral equation (IE, or field panel) method has been developed to predict potential transonic flows around two-dimensional configurations, using the panel method approach. Compressibility is taken into account by a distribution of sources in the field. Shock waves are captured using type-dependent differencing in the evaluation of the field sources. Since no inflow or outflow boundary conditions need to be imposed and the sources' strength declines rapidly away from the airfoil(s), only a small computational domain is necessary. The method also has the advantage in that the field grid does not need to be body conforming, allowing use of a Cartesian mesh. The code was evaluated for subcritical and supercritical flows on the NACA 0012, NACA 64A010, RAE 2822, and Williams B airfoils. Subcritical results were found to be in very good agreement with other data from IE methods, although comparison with finite difference (FD) data shows a tendency to underpredict lift considerably. In comparison with FD transonic results, the location of shocks was predicted well, but these usually are weaker and more spread. Agreement with other IE methods for transonic flows is also very good. Author (CISTI)

SURFACE HOT FILM MEASUREMENTS AT ATTAS LAMINAR GLOVE [OBERFLAECHENHEISSFILMMESSUNGEN AM ATTAS-LAMINARHANDSCHUH] **c05**
H.-P. Kreplin and G. Hoehler *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 1-11 In GERMAN (For primary document see N94-22597 05-02)
Avail: CASI HC A03/MF A02

The surface hot film technique, which was used for free flight tests with the German research aircraft ATTAS, is described. The experiments were carried out in order to obtain criteria for the laminar turbulent boundary transition in swept wings in the framework of a research program on transonic laminar wings. The surface hot film technique was used for observing unstationary processes with high time resolution. V-shaped double sensors were used. The sensors are made of two nickel films on a thin plastic foil. Nine sensors were mounted in the middle section of the glove, and two sensors were located in internal and external glove sides on the nose. All were operated with constant temperature anemometers in the aircraft cabin. The probability distributions of laminar and turbulent signals amplitudes are shown to be similar to a Gaussian distribution. The intermittency factor could be evaluated considering the cumulative amplitude distribution function. It is concluded that the method is useful provided perturbations such as electronic noise do not influence the information.

TESTING OF A MULTISENSOR HOT FILM TECHNIQUE IN WIND TUNNEL AND FREE FLIGHT [ERPROBUNG EINER NEUENTWICKELTEN MULTISENSOR-HEISSFILMTECHNIK IM WINDKANAL UND FREIFLUG]
M. Kornberger and F. Feyzi *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 12-20 In GERMAN (For primary document see N94-22597 05-02)
Avail: CASI HC A02/MF A02

A multisensor hot film measurement technique, which allows ninety-six sensors to be simultaneously operated on a polyimide foil and was used in free flight tests of laminar gloves, is described. The technique was also used for transition estimation in a low speed wind tunnel; angle of incidence and flow velocity were chosen as the experiment parameters. Each hot film was calibrated with a comparative measuring process for estimation of magnitude and direction of wall shear stress vector. The results were transferred to the multisensor technique as far as possible. Another calibration method, which is based on the solution of heat transfer balance equations for a hot film, was developed in order to take into account heat conduction, which was calculated for a rotation symmetric body. The CPM3 (Computational Preston Tube) method and the piezo array technique are compared in terms of functionality for laminar turbulent boundary layer transition investigations. The CPM3 technique is based on static pressure measurement from three wall Pitot probes of differential pressure sensors; the local wall shear stress is obtained from measured velocities in correlation with the effective wall distance by adaptation of the proportionality factor between mixture length and wall distance.

Piezoelectric foils are used in multisensor arrays as electromagnetic converters for detection of wall pressure oscillations. Because of their high sensitivity and flexibility, they are particularly suited to examination of unstationary wall forces and can be mounted on an airfoil surface without perturbation. Wind tunnel measurements were carried out in order to establish static pressure probe reliability. Results of wall friction distributions with different angles of incidence are presented and compared with data calculated using the Eppler code. ESA

Avail: CASI HC A03/MF A02

The capability of a fluid deicing system for transonic laminar wing cleaning is tested with the ATTAS research aircraft. The ATTAS is a twin jet regional airplane. A panel of the original, coarsely porous deicing system was exchanged for a specially produced titanium plate with laser drilled holes, which were regularly located on the surface; an equivalent surface was defined as a reference panel and searchlight was mounted between both panels. A standard deicing liquid, made of 80 percent water and 20 percent glycol, was tested as well as three other liquids, with different additives which modify the viscosity. Testing free parameters were adjustable liquid quantity, flight velocity, and liquid viscosity as a function of temperature. All flights took place in low altitudes in order to obtain statistical distribution of dirtiness. The cleanliness results were measured with digital image processing and the residual dirtiness was estimated with roughness measurements. The tests are found to be reproducible and easily automatable. ESA

MEASUREMENT OF THE INFLUENCE OF DEICING LIQUIDS ON AIRCRAFT AERODYNAMICS [DIE MESSUNG DES EINFLUSSES VON ENTEISUNGSFLUESSIGKEITEN AUF DIE AERODYNAMIK DES FLUGZEUGES]

U. Rummelmann *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 57-63 In GERMAN (For primary document see N94-22597 05-02)
Avail: CASI HC A02/MF A02

Flight tests were carried out in the all engine operating case in order to determine the influence of four different deicing liquids on Boeing 737-200 aerodynamics. Two different slat/flap positions were considered in this investigation. For local film thickness a measuring process was developed. The process was based on laser sensors. The data were enhanced by video, photography, and movie recordings. The role of liquid density and temperature was examined. Drag resistance and lift variations were obtained using a high velocity PCM (Pulse Code Modulation) data acquisition facility; this system was used as the data source for the airborne data analysis and monitoring system, which allows data quality to be evaluated. The following data were obtained and studied: static and dynamic pressures, wind velocity and direction, ground proximity data, and trim angle of the tailplane. ESA

The operating principles of the ALEV3 three axis laser Doppler anemometer, which was designed for flight tests with the A-320 and A-340 aircraft, are depicted. If mounted on the aircraft center of gravity, the ALEV-3 allows true flight velocity in three directions and angles of attack and sideslip to be directly measured with a very good accuracy, in particular flight areas such as limit buffeting, stall, high Mach numbers, or sideslip flights. Aircraft parameter estimation, calculation, and calibration results are presented. The accuracies of velocity, static pressure and aerodynamic angle measurements were compared with classical anemometers precisions. Flight tests results of the ALEV-1 one axis laser anemometer for A-320 are given as a reference. ESA

HOT WIRE ANEMOMETRY: A VERSATILE INSTRUMENTATION USED FOR PREDEVELOPMENT STUDIES AND FLIGHT TESTING OF THE DO-328 AIRCRAFT [HITZDRAHTANEMOMETRIE: EIN VIELSEITIGES INSTRUMENTARIUM IM EINSATZ BEI VORENTWICKLUNG UND FLUGVERSUCH DER DO 328] **c35**

P. Dick *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 82-96 In GERMAN (For primary document see N94-22597 05-02)
Avail: CASI HC A03/MF A02

The qualities of hot wire anemometry measuring techniques for laboratory experiments, mock-ups, and flight tests are examined in the framework of the development of the Do-328 regional airliner. Probes for velocity measurements were calibrated in a small wind tunnel. The wind tunnel was designed to produce very low flow velocities. The method is shown to be particularly useful in the following cases: multichannel flowmeters for measuring the trim of air flux in tube systems; ventilation comfort indicators in an aircraft cabin; and test instruments for the flow configuration in free flow and boundary layers. RIBLET BOUNDARY LAYER MEASUREMENTS OF AN A-310 FUSELAGE WITH PITOT COMBS [RIBLET-GRENZSCHICHTMESSUNGEN AN EINEM A320-RUMPF MIT PITOT - RECHEN]

F. X. Muench and R. Henke *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 97-110 In GERMAN (For primary document see N94-22597 05-02)
Avail: CASI HC A03/MF A02

Preparation, running, and results of global measurements for a flight test of riblet effects with the A-320 aircraft are presented. The following activities are reported: three dimensional boundary layer calculation for estimation of wall stream line direction, wall shear stress distribution and boundary layer thickness, choice of riblet location on the aircraft, and preparation of the local measurements of velocity profiles at some chosen parts of the aircraft. For the boundary layer measurements, two Pitot combs were mounted one behind the other on the fuselage upper side. Pressure values, Mach number, calibrated flight velocity, altitude, lift coefficient, angles of attack, and sideslip and vertical and lateral accelerations were recorded on magnetic tape. The method is found to be reproducible, insensitive to aircraft vibrations and useful for obtaining information about riblet effects. ESA

IMAGE PROCESSING AS A TOOL IN FLIGHT TESTING EVALUATION **c35**

Anders Kaelldahl *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 111-117 (For primary document see N94-22597 05-02)
Avail: CASI HC A02/MF A02

An advanced system for digitizing and automatically analyzing film and video images and its adaptation for specific purposes are described. A video camera of charge coupled devices type was installed in a Viggen test aircraft and flight tests of sensitivity for different wavelengths and measurable resolution were carried out. A video tape containing interesting runs was input into an image processing system in order to show that the video based system meets the specification for Head Up Display (HUD) evaluation. A market investigation was undertaken for an image processing system for HUD evaluation, with particular requirements on a high performance time base corrector in the video input unit, video disks, image processor, and display unit. A digital video disk system and a tracking algorithm based on correlation methods were chosen; the image processing system was completed with a film scanner for converting cinema films into a digital format. In addition to the HUD analysis technique, a photogrammetric system was used for testing microwave landing, radar altimeter, or third category landing system. It is concluded that this image processing system

provides evaluation time reduction, higher possibility for correct evaluation and higher accuracy since more points from each image are used. ESA

RECENT ONERA CONTRIBUTIONS TO THE DEVELOPMENT OF FLIGHT TEST MEASUREMENT TECHNIQUES
V. Schmitt, D. Arnal (Centre d'Etudes et de Recherches, Toulouse, France.), and J. J. Thibert *In* Tech. Univ. Berlin, Measurement Technology for Flight Tests May 1991 p 118-129 (For primary document see N94-22597 05-02)
Avail: CASI HC A03/MF A02

Activities in flight testing are summarized with an emphasis on particular requirements and specifications to achieve the required quality of the results. Some examples for both surface measurements and flow field measurement techniques are given. They were related to a variety of topics such as high lift investigations, transonic drag rise evaluation, riblet effects on boundary layers or wakes, and laminar flow research. These examples show that there is an increasing need for flow investigations in flight tests to validate wind tunnel or computer simulations. ESA

William H. Wentz, Jr., David Ellis, and Steve Hooper 1993 33 p
(NIAR-93-4) Avail: CASI HC A03/MF A01

In this National Institute for Aviation Research (NIAR) report to the FAA, goals included automatic target tracking to extract head motion during crash tests. Associated tasks included a crash analysis of aircraft seats and an analysis of commuter seat-type structures in a crash environment to study energy absorbing mechanics of seat structures subject to emergency landing conditions. One task was to evaluate and enhance the biodynamic analysis of the occupant responses for evaluation of aircraft crash safety. Another task was the bonded/fusion repair of aircraft structures to qualify a procedure for the assessment and repair of metallic and composite structures. The effects of mechanical paint removal on surface morphology and fatigue behavior of composite materials was studied. A test method was developed for the assessment of the integrity of bonded joints and composite materials; addressed features include cyclic loading and freeze/thaw moisture conditioning. With regards to regional/commuter aircraft flight loads, robotic assistance to aircraft inspection was studied and a robot was developed. Human factors in the cockpit were studied to improve the understanding of single pilot terminal area operations, with emphasis on flight guidance displays. There was also a task toward standardization of design procedures for turbine rotor containment. Proposals are included in the report with their goals, approach, and status. CASI

WINDSHEAR DETECTION FOR AIRCRAFT USING TEMPERATURE LAPSE RATE Patent
Terry L. Zweifel, inventor (to Honeywell, Inc.) 11 Feb. 1992 44 p Filed 2 Nov. 1988
(CA-Patent-1,295,736; Int-Patent-Class-G08B-31/00; CTN-93-60639)
Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

An on-board aircraft system is described that provides an indication of wind shear probability considerably before prior art systems. A measurement of temperature change with altitude (temperature lapse rate) is made, filtered to eliminate noise, and compared to the dry adiabatic temperature lapse rate: the latter being indicative of unstable air. When the measured or empirical temperature lapse rate is less than the dry adiabatic temperature lapse rate for a predetermined number of measurements, a cautionary message is relayed to the flight crew with a caution light. The same cautionary message may be transmitted to the landing airport to be used to caution other aircraft and may also be used to enhance the detection capability of existing on-board prior art systems. If a cautionary message has been generated and the aircraft enters a region of rapidly decreasing temperature as is usually present in the downflow of a microburst, a warning message is generated alerting the flight crew to take immediate action to exit the condition. The warning message may also be transmitted to the landing airport and used to warn other aircraft and/or used to enhance the detection capability of existing on-board prior art systems.

AVIATION SAFETY RESEARCH. VOLUME 1: LITERATURE REVIEW OF SOURCES OF AVIATION ACCIDENT AND INCIDENT DATA AND SELECTED FACTORS CONTRIBUTING TO ACCIDENTS
R. G. Mortimer and J. S. Hanson 7 May 1993 216 p Sponsored by Construction Engineering Research Lab. (Army), Champaign, IL Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DACA88-90-D-0028-28)
(PB93-202885; SAFETY RESEARCH-93-1-Vol-1) Avail: CASI HC A10

The report is Volume 1 in studies of aviation accidents. The emphasis is on general aviation, but Part 135 and 121 operations are also discussed. It is a review of the literature of sources of aviation accident and exposure data and of selected factors affecting safety in aviation. Among topics covered are: epidemiological studies, weather factors, induced pilot error, and the stall accident. It is believed that improved aerodynamic design, using available knowledge, could reduce stall/spin accidents by 10%.

Weather is a primary cause in about 18% of all accidents and in 32% of fatal accidents, and is a major contributor to accidents of general and commercial aviation. Alcohol is now involved in about 5% of pilots who are fatally injured, but about 12% have used therapeutic drugs and 3% illicit drugs. NTIS

USERS MANUAL FOR THE NASA LEWIS THREE-DIMENSIONAL ICE ACCRETION CODE (LEWICE 3D)
Colin S. Bidwell and Mark G. Potapczuk Dec. 1993 143 p Sponsored by NASA. Washington
(RTOP 505-68-10)
(NASA-TM-105974; E-7847; NAS 1.15:105974) Avail: CASI HC A07/MF A02

A description of the methodology, the algorithms, and the input and output data along with an example case for the NASA Lewis 3D ice accretion code (LEWICE3D) has been produced. The manual has been designed to help the user understand the capabilities, the methodologies, and the use of the code. The LEWICE3D code is a conglomeration of several codes for the purpose of calculating ice shapes on three-dimensional external surfaces. A three-dimensional external flow panel code is incorporated which has the capability of calculating flow about arbitrary 3D lifting and nonlifting bodies with external flow. A fourth order Runge-Kutta integration scheme is used to calculate arbitrary streamlines. An Adams type predictor-corrector trajectory integration scheme has been included to calculate arbitrary trajectories. Schemes for calculating tangent trajectories, collection efficiencies, and concentration factors for arbitrary regions of interest for single droplets or droplet distributions have been incorporated. A LEWICE 2D based heat transfer algorithm can be used to calculate ice accretions along surface streamlines. A geometry modification scheme is incorporated which calculates the new geometry based on the ice accretions generated at each section of interest. The three-dimensional ice accretion calculation is based on the LEWICE 2D calculation. Both codes calculate the flow, pressure distribution, and collection efficiency distribution along surface streamlines. For both codes the heat transfer calculation is divided into two regions, one above the stagnation point and one below the stagnation point, and solved for each region assuming a flat plate with pressure distribution. Water is assumed to follow the surface streamlines, hence starting at the stagnation zone any water that is not frozen out at a control volume is assumed to run back into the next control volume. After the amount of frozen water at each control volume has been calculated the geometry is modified by adding the ice at each control volume in the surface normal direction. Author (revised)

AIRCRAFT CABIN WATER SPRAY DISBENEFITS STUDY Final Report
Thomas L. Reynolds and Kent W. Porter Oct. 1993 137 p Sponsored in part by FAA
(Contract NAS1-18027)
(NASA-CR-194750; NAS 1.26:194750; DOT/FAA/CT-92/6) Avail: CASI HC A07/MF A02

The concept of utilizing a cabin water spray system (CWSS) as a means of increasing passenger evacuation and survival time following an accident has received considerable publicity and has been the subject of testing by the regulatory agencies in both the United States and Europe. A test program, initiated by the CAA in 1987, involved the regulatory bodies in both Europe and North America in a collaborative research effort to determine the benefits and 'disbenefits' (disadvantages) of a CWSS. In order to obtain a balanced opinion of an onboard CWSS, NASA, and FAA requested the Boeing Commercial Airplane Group to investigate the potential 'disbenefits' of the proposed system from the perspective of the manufacturer and an operator. This report is the result of a year-long, cost-sharing contract study between the Boeing Commercial Airplane Group, NASA, and FAA. Delta Air Lines participated as a subcontract study team member and investigated the 'return to service' costs for an aircraft that would experience an uncommanded operation of a CWSS without the presence of fire. Disbenefits identified include potential delays in evacuation, introduction of 'common cause failure' in redundant safety of flight systems, physiological problems for passengers, high cost of refurbishment for inadvertent discharge, and potential to negatively affect other safety systems. INTERVENTION STRATEGIES FOR THE MANAGEMENT OF HUMAN ERROR
Earl L. Wiener Aug. 1993 114 p
(Contract NCA2-441)
(NASA-CR-4547; A-93120; NAS 1.26:4547) Avail: CASI HC A06/MF A02

This report examines the management of human error in the cockpit. The principles probably apply as well to other applications in the aviation realm (e.g. air traffic control, dispatch, weather, etc.) as well as other high-risk systems outside of aviation (e.g. shipping, high-technology medical procedures, military operations, nuclear power production). Management of human error is distinguished from error prevention. It is a more encompassing term, which includes not only the prevention of error, but also a means of disallowing an error, once made, from adversely affecting system output. Such techniques include: traditional human factors engineering, improvement of feedback and feedforward of information from system to crew, 'error-evident' displays which make erroneous input more obvious to the crew, trapping of errors within a system, goal-sharing between humans and machines (also called 'intent-driven' systems), paperwork management, and behaviorally based approaches, including procedures, standardization, checklist design, training, cockpit resource management, etc. Fifteen guidelines for the design and implementation of intervention strategies are included. ROTORCRAFT LOW ALTITUDE IFR BENEFIT/COST ANALYSIS: CONCLUSIONS AND RECOMMENDATIONS Final Report
Robert K. Anoli, Robert B. Newman, and Edwin D. McConkey Oct. 1993 152 p
(Contract DTFA01-87-C-00014)
(DOT/FAA/RD-93/22; DOT/FAA/DS-89/11; SCT-92RR-8) Avail: CASI HC A08/MF A02

The Rotorcraft Master Plan advocates the establishment of additional communications, navigation, and surveillance (CNS) facilities, as well as the analysis and development of systems to satisfy the increasing demand for widespread instrument flight rules (IFR) rotorcraft operations within the National Airspace System (NAS). The objective of this study is to determine if there is an economic basis for improvement of these low altitude IFR services within the NAS in order to better support rotorcraft IFR operations. The findings of this study will aid FAA decision making in that regard. In view of prior implementation decisions on LORAN-C and GPS, the emphasis in this effort is on communications, surveillance, procedural changes, and

avionics. This report is the last of a series of three reports that address rotorcraft low altitude benefit/cost analysis. The other two are: Rotorcraft Low Altitude CNS Benefit/Cost Analysis: Operations Data, DOT/FAA/DS-89/9, and Rotorcraft Low Altitude IFR Benefit/Cost Analysis: Operations Analysis, DOT/FAA/RD-89/10. This final report reviews the operational requirements and constraints for specific rotorcraft missions identified in the previous reports in this series. It also reviews all of the alternatives identified for improving rotorcraft operations. The alternatives considered include additional communications and surveillance equipment, both existing equipment and future systems identified in the Aviation Systems Capital Investment Plan (CIP), and the air traffic control (ATC) procedural changes. A benefit/cost (B/C) analysis is conducted for each communication, surveillance, and procedural improvement identified. When site specific data is available, it is used to calculate actual B/C ratios. When no data exists, a break-even analysis is provided. Author

AUTOMATIC AVHRR IMAGE NAVIGATION SOFTWARE Final Report

Dan Baldwin and William Emery 1992 10 p

(Grant NAGw-3224)

(NASA-CR-194602; NAS 1.26:194602) Avail: CASI HC A02/MF A01

This is the final report describing the work done on the project entitled Automatic AVHRR Image Navigation Software funded through NASA-Washington, award NAGW-3224, Account 153-7529. At the onset of this project, we had developed image navigation software capable of producing geo-registered images from AVHRR data. The registrations were highly accurate but required a priori knowledge of the spacecraft's axes alignment deviations, commonly known as attitude. The three angles needed to describe the attitude are called roll, pitch, and yaw, and are the components of the deviations in the along scan, along track and about center directions. The inclusion of the attitude corrections in the navigation software results in highly accurate georegistrations, however, the computation of the angles is very tedious and involves human interpretation for several steps. The technique also requires easily identifiable ground features which may not be available due to cloud cover or for ocean data. The current project was motivated by the need for a navigation system which was automatic and did not require human intervention or ground control points. The first step in creating such a system must be the ability to parameterize the spacecraft's attitude. The immediate goal of this project was to study the attitude fluctuations and determine if they displayed any systematic behavior which could be modeled or parameterized. We chose a period in 1991-1992 to study the attitude of the NOAA 11 spacecraft using data from the Tiros receiving station at the Colorado Center for Astrodynamic Research (CCAR) at the University of Colorado. ALL-WEATHER PRECISION LANDING SYSTEM FOR AIRCRAFT IN REMOTE AREAS Patent

Gerald E. Hart, inventor (to Navy) 4 May 1993 16 p Filed 24 Jul. 1990

(AD-D015924; US-Patent-5,208,601; US-Patent-Appl-SN-556606) Avail: US Patent and Trademark Office

An all-weather aircraft landing system includes a plurality of ground based passive 90 deg dihedral reflectors for producing two-bounce reflected signals without ground reflections and an airborne radar system which may transmit and receive same sense circularly polarized radiation, while completely rejecting opposite sense polarization returns or else utilizing them to indicate weather conditions. Radar clutter from objects such as rain, buildings, and trees which produce opposite sense reflections are rejected by the same sense receiver or switched to an opposite sense receiver to provide weather/obstacle condition information. By properly orienting a plurality of 90 deg dihedral angle reflectors of a particular size in a predetermined array pattern and tilt-angle adjacent a runway, the reflections from airborne radar signals are processed and displayed to provide a visual means for determining glide slope deviation and approach vector of the landing aircraft. A SOFTWARE ARCHITECTURE FOR A SMALL AUTONOMOUS UNDERWATER VEHICLE NAVIGATION SYSTEM M.S. Thesis

Clark D. Stevens Jun. 1993 153 p

(AD-A272322) Avail: CASI HC A08/MF A02

This thesis documents the development of an interim Small Autonomous Underwater Vehicle (AUV) Navigation System (SANS), a self-contained, externally mountable navigation package. The purpose of SANS is to determine the position of a submerged object of interest located by an AUV. The volume of SANS must not exceed 120 cubic inches and total system accuracy of 10.0 meters rms or better is required. An Inertial Navigation System (INS) is implemented to compute the ascent path during transit from an object of interest to the surface. INS hardware components include miniature spin gyroscopes, a compass, and a depth transducer interfaced through an analog to digital converter. Global Positioning System (GPS) is used to determine the AUV's location after reaching the surface. The reciprocal of the ascent vector is applied to the AUV's GPS position to accurately determine the location of the target of interest. A primarily object-oriented software architecture is implemented here with extensive software testing to verify the proper operation of key modules. The objective of this thesis is to quantify the adequacy of the selected components in meeting these requirements and to develop a breadboard design demonstrating the basic functions of the interim SANS. This research concludes that the components selected for the interim SANS meet the accuracy requirements provided the AUV maintains a climb angle which is equal to or steeper than 12 degrees from a typical mission depth of 20 meters. DEVELOPMENT AND EVALUATION OF A PROFILE NEGOTIATION PROCESS FOR INTEGRATING AIRCRAFT AND AIR TRAFFIC CONTROL AUTOMATION

Steven M. Green, Wim denBraven (National Aerospace Lab., Amsterdam, Netherlands.), and David H. Williams (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.) Apr. 1993 23 p Presented at the RTCA 1991 Annual Assembly Meeting and Technical Symposium

(RTOP 505-64-13)

(NASA-TM-4360; A-92038; NAS 1.15:4360) Avail: CASI HC A03/MF A01

The development and evaluation of the profile negotiation process (PNP), an interactive process between an aircraft and air traffic control (ATC) that integrates airborne and ground-based automation capabilities to determine conflict-free trajectories that are as close to an aircraft's preference as possible, are described. The PNP was evaluated in a real-time simulation experiment conducted jointly by NASA's Ames and Langley Research Centers. The Ames Center/TRACON Automation System (CTAS) was used to support the ATC environment, and the Langley Transport Systems Research Vehicle (TSRV) piloted cab was used to simulate a 4D Flight Management System (FMS) capable aircraft. Both systems were connected in real time by way of voice and data lines; digital datalink communications capability was developed and evaluated as a means of supporting the air/ground exchange of trajectory data. The controllers were able to consistently and effectively negotiate nominally conflict-free vertical profiles with the 4D-equipped aircraft. The actual profiles flown were substantially closer to the aircraft's preference than would have been possible without the PNP. However, there was a strong consensus among the pilots and controllers that the level of automation of the PNP should be increased to make the process more transparent. The experiment demonstrated the importance of an aircraft's ability to accurately execute a negotiated profile as well as the need for digital datalink to support advanced air/ground data communications. The concept of trajectory space is proposed as a comprehensive approach for coupling the processes of trajectory planning and tracking to allow maximum pilot discretion in meeting ATC constraints. Author (revised)

TECHNIQUES USED FOR THE ANALYSIS OF OCULOMETER EYE-SCANNING DATA OBTAINED FROM AN AIR TRAFFIC CONTROL DISPLAY

Daniel J. Crawford, Daniel W. Burdette, and William R. Capron Dec. 1993 184 p

(Contract NAS1-19000; RTOP 505-64-13-01)

(NASA-CR-191559; NAS 1.26:191559) Avail: CASI HC A09/MF A02

The methodology and techniques used to collect and analyze look-point position data from a real-time ATC display-format comparison experiment are documented. That study compared the delivery precision and controller workload of three final approach spacing aid display formats. Using an oculometer, controller lookpoint position data were collected, associated with gaze objects (e.g., moving aircraft) on the ATC display, and analyzed to determine eye-scan behavior. The equipment involved and algorithms for saving, synchronizing with the ATC simulation output, and filtering the data are described. Target (gaze object) and cross-check scanning identification algorithms are also presented. Data tables are provided of total dwell times, average dwell times, and cross-check scans. Flow charts, block diagrams, file record descriptors, and source code are included. The techniques and data presented are intended to benefit researchers in other studies that incorporate non-stationary gaze objects and oculometer equipment. Author (revised)

PARALLEL RUNWAY REQUIREMENT ANALYSIS STUDY. VOLUME 1: THE ANALYSIS Final Report
Yaghoob S. Ebrahimi Dec. 1993 129 p
(Contract NAS1-18027; RTOP 505-66-41-04)
(NASA-CR-191549-Vol-1; NAS 1.26:191549-Vol-1) Avail: CASI HC A07/MF A02

The correlation of increased flight delays with the level of aviation activity is well recognized. A main contributor to these flight delays has been the capacity of airports. Though new airport and runway construction would significantly increase airport capacity, few programs of this type are currently underway, let alone planned, because of the high cost associated with such endeavors. Therefore, it is necessary to achieve the most efficient and cost effective use of existing fixed airport resources through better planning and control of traffic flows. In fact, during the past few years the FAA has initiated such an airport capacity program designed to provide additional capacity at existing airports. Some of the improvements that that program has generated thus far have been based on new Air Traffic Control procedures, terminal automation, additional Instrument Landing Systems, improved controller display aids, and improved utilization of multiple runways/Instrument Meteorological Conditions (IMC) approach procedures. A useful element to understanding potential operational capacity enhancements at high demand airports has been the development and use of an analysis tool called The PLAND—BLUNDER (PLB) Simulation Model. The objective for building this simulation was to develop a parametric model that could be used for analysis in determining the minimum safety level of parallel runway operations for various parameters representing the airplane, navigation, surveillance, and ATC system performance. This simulation is useful as: a quick and economical evaluation of existing environments that are experiencing IMC delays, an efficient way to study and validate proposed procedure modifications, an aid in evaluating requirements for new airports or new runways in old airports, a simple, parametric investigation of a wide range of issues and approaches, an ability to tradeoff air and ground technology and procedures contributions, and a way of considering probable blunder mechanisms and range of blunder scenarios. This study describes the steps of building the simulation and considers the input parameters, assumptions and limitations, and available outputs. Validation results and sensitivity analysis are addressed as well as outlining some IMC and Visual Meteorological Conditions (VMC) approaches to parallel runways. Also, present and future applicable technologies (e.g., Digital Autoland Systems, Traffic Collision and Avoidance System II, Enhanced Situational Awareness System, Global Positioning Systems for Landing, etc.) are assessed and recommendations made.

PARALLEL RUNWAY REQUIREMENT ANALYSIS STUDY. VOLUME 2: SIMULATION MANUAL Final Report
Yaghoob S. Ebrahimi and Ken S. Chun Dec. 1993 51 p
(Contract NAS1-18027; RTOP 505-66-41-04)
(NASA-CR-191549-Vol-2; NAS 1.26:191549-Vol-2) Avail: CASI HC A04/MF A01

This document is a user manual for operating the PLAND—BLUNDER (PLB) simulation program. This simulation is based on two aircraft approaching parallel runways independently and using parallel Instrument Landing System (ILS) equipment during Instrument Meteorological Conditions (IMC). If an aircraft should deviate from its assigned localizer course toward the opposite runway, this constitutes a blunder which could endanger the aircraft on the adjacent path. The worst case scenario would be if the blundering aircraft were unable to recover and continue toward the adjacent runway. PLAND—BLUNDER is a Monte Carlo-type simulation which employs the events and aircraft positioning during such a blunder situation. The model simulates two aircraft performing parallel ILS approaches using Instrument Flight Rules (IFR) or visual procedures. PLB uses a simple movement model and control law in three dimensions (X, Y, Z). The parameters of the simulation inputs and outputs are defined in this document along with a sample of the statistical analysis. This document is the second volume of a two volume set. Volume 1 is a description of the application of the PLB to the analysis of close parallel runway operations.

A ROBUST QUALITY CONTROL SYSTEM FOR GPS NAVIGATION AND KINEMATIC POSITIONING Ph.D. Thesis
Goa Yang Sep. 1992 171 p
(ISBN-0-315-83148-0; CTN-94-60938) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The development and testing of a robust quality control system for global positioning system (GPS) navigation and kinematic positioning is described. The system is built upon the successful combination of well-known classical statistics with modern robust statistics. The theory of robust statistics was applied to make robust the standard Kalman filter and to formulate a robust failure signal generation function. Good performance in failure detection and failure identification, minimum implementation effort, and automation are the main criteria employed in the development of the system. Theoretical and numerical aspects of system modelling are presented along with the introduction of important concepts and the derivation of useful equations. Both the computational load and implementation effort were reduced to a minimum through various numerical techniques. The system was tested by applying it to integrity monitoring in GPS navigation and cycle slip detection and identification in GPS kinematic positioning. Results show that significant improvements have been achieved as compared to the conventional innovation based approach.

DEVELOPMENT AND OPERATION OF THE F/A-18 MODEL CONTROL SURFACE ACTUATORS
S. S. Lam and Y. Y. Link Aug. 1993 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271330; ARL-TN-29; DODA-AR-008-345) Avail: CASI HC A03

A series of test programs in the ARL 2.7m x 2.1m Low Speed Wind Tunnel of a 1/9th scale model of the F/A-18 required the development of a software package to drive the control surfaces. This software is written in VAX FORTRAN for a MicroVAX 2 computer. The software communicates with the model through a specially designed Actuator Module that responds to requests from the MicroVAX 2 computer. In order to establish the relationship between control surface angles and Linear Variable Differential Transformer readings a cubic spline interpolation method has been implemented. This report describes the development and operation of the control surface actuators' software and contains a detailed guide for its use. DTIC

AUDIT REPORT. NAVY'S AIRCRAFT STRUCTURAL LIFE SURVEILLANCE PROGRAM DATA RECORDERS
12 Nov. 1992 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A270391; IG/DOD-93-022) Avail: CASI HC A03

We are providing this final report for your information and use. This audit was performed in response to a DoD Inspector General hotline allegation that the Navy's planned $188 million procurement of structural data recorders under the Navy's Aircraft Structural Life Surveillance Program duplicated existing Navy recorder systems. The recorder monitors the structural stress that an aircraft experiences during operation. Our objective was to evaluate the validity of this allegation. The effectiveness of applicable internal controls was also evaluated. The Navy's Aircraft Structural Life Surveillance Program data recorder does not duplicate any existing Navy recorder systems. The structural data recorder does duplicate functions of a similar Air Force system. However, it is no longer practicable or economical for the Navy and the Air Force to combine their structural recorder systems because both have already installed and integrated these recorder systems in substantial numbers of aircraft. PROCEEDINGS OF THE TWENTIETH ANNUAL TECHNOLOGYFEST
1993 25 p Technologyfest held in Wichita, KS, 12-13 Nov. 1993; cosponsored by AIAA
Avail: CASI HC A03/MF A01

The program for the twentieth annual Techfest held November 12 - 13, 1993 is accompanied by abstracts of selected topics. Design topics include a supersonic oblique all-wing transport aircraft, an application of neural networks to airfoil design, aircraft nosewheel steering simulation, an alternative parameter airfoil optimization method, a high altitude long endurance aircraft with manufacturing considerations, and integrated design of controllers with bang bang and proportional control effectors. Structures topics include reducing structural loads, failure of aircraft structures due to internal blast, and geriatrics of commercial airplanes. Aerodynamics topics include visualization of the multiple supersonic jet oscillations by swept focused strobed schlieren technique, the near-wake flow behavior of an oscillating airfoil with modified trailing edge, full span flaperons for a biplane, an experimental investigation of helicopter rotor downwash and tail boom interaction at the WSU 7 x 10 foot wind tunnel, and incorporating biplane wing theory into a large subsonic all-cargo transport. CONTROL VANE GUIDANCE FOR A DUCTED-FAN UNMANNED AIR VEHICLE M.S. Thesis
Patrick J. Moran Jun. 1993 112 p
(AD-A271957) Avail: CASI HC A06/MF A02

Control of airborne vehicles was originally conceived to be done entirely by human pilots. Improvements in electronics in the last 50 years have allowed many flight control functions to become automated, with the pilot continuously monitoring flight parameters from within the vehicle cockpit. With the advent of small unmanned air vehicles (UAV's) which are limited in size and weight-carrying capacity, a pilot is now able to fly an airborne vehicle from a distant ground-fixed position. Miniature electronic instruments control or direct vehicle movements either through pilot commands or autonomously. In order to accomplish reliable, continuous control of a UAV, many sensors are necessary aboard the vehicle. This thesis designed and installed necessary hardware and developed software to guide a UAV's aerodynamic control vanes, with feedback from sensors aboard the vehicle, in order to facilitate ground-based pilot control. Previous thesis work accomplished on this project achieved control of a UAV, named Archytas, in one degree-of-freedom, roll, while mounted on a test stand. Umbilical-controlled guidance of Archytas' control vanes from a forward-mounted sensor pod was set as the goal for this phase of the Archytas project. This work focused on modification of hardware to generate and access required signals, programming of analog-to-digital (A/D) and counter/timer peripheral boards mounted in a personal computer to control electrical and signal flow, and implementation of single-input-single-output (SISO) control equations developed concurrently in another thesis. TORSION SPRING POWERED MISSILE WING DEPLOYMENT SYSTEM Patent
Arthur M. Frank, inventor (to Grumman Aerospace Corp.) 18 Aug. 1992 16 p Filed 28 May 1987
(CA-Patent-1,306,384; Int-Patent-Class-B64C-3/56;
Int-Patent-Class-F42B-10/18; CTN-93-60687) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

A foldable wing deployment system is provided for a missile having a foldable wing section hinged to a fixed wing section. An overcenter linkage

connects the fixed and foldable wing section for securely deploying the foldable wing section to a coextensive position with the fixed wing section. A first torsion bar having a first end is connected to a first gear, and a hollow cylindrical torsion member is mounted over the torsion bar. A first end of the member is fixed and a second end is connected to a corresponding second end of the torsion bar. A second torsion bar is located in parallel proximity to the cylindrical torsion member and is connected to the overcenter linkage. A second gear is mounted on the second torsion bar and contacts the first gear for exerting supplementary bias on the overcenter linkage during its initial operation for ensuring a substantially linear actuating drive on the linkage, necessary for smooth and reliable wing deployment. LOW-COST, DUAL-USE PLATFORMS FOR ENVIRONMENTAL SENSING, PHASE 1
Matthew G. Hutchison, John S. Langford, and Charles S. Preston 1993 47 p
(Contract N00014-93-C-0037)
(AD-A272951; AR-9305) Avail: CASI HC A03/MF A01

Recent advances in microelectronics, lightweight composite structures, and computational fluid mechanics have made possible a new generation of semi-autonomous, unmanned aircraft. Many of these unmanned aerial vehicles (UAV's) were originally conceived for purely military purposes, but the performance capabilities--in particular, the capacity for flights of extended range and endurance--have attracted the attention of the atmospheric and environmental research communities. While the application of UAV's to high-altitude research has been extensively investigated and documented, much less attention has been given to their potential role in low-altitude atmospheric studies. This report focuses on the application of unmanned aircraft to environmental sensing at low altitudes in the marine environment. There appear to be a number of missions in which a suitable UAV platform could provide unique opportunities for data collection that would greatly expand the current understanding of this vital region of the atmosphere. In addition to scientific contributions, the information collected at low altitude would also be of significant interest to the U.S. Navy for purposes varying from calibration of weapons guidance systems to initialization of computational models. DESIGN, FABRICATION AND TEST OF A VERTICAL ATTITUDE TAKEOFF AND LANDING UNMANNED AIR VEHICLE M.S. Thesis
Robert B. Stoney Jun. 1993 234 p
(AD-A273003) Avail: CASI HC A11/MF A03

Future fleet needs for real-time intelligence require an unmanned platform capable of operations from small surface combatants without the need for extensive support personnel and equipment and without causing disruption to the operations of the ship from which it operates. A candidate must not only takeoff and land vertically but also be capable of high forward flight speeds and efficient on-station performance. The design and initial fabrication of a Vertical Attitude Takeoff and Landing (VATOL) Unmanned Air Vehicle (UAV) airframe was completed at the Naval Postgraduate School. The vehicle, called Archytas, was a combination of two existing UAV's--the AROD and Aquila--as well as locally manufactured components, including a canard and wing spar. The objective of creating Archytas was to provide a proof-of-concept platform for research to explore performance trade-offs and stability augmentation. A three-degree-of-freedom simulation was used as the focus of the design efforts, to validate design decisions made in the fields of propulsion, aerodynamics, structures and flight mechanics. Engine tests were conducted to determine thrust and control power. Structural components were designed, fabricated and then tested, making modifications where necessary to ensure sufficient airframe strength. A longitudinal control system was designed, validated by simulation, and tested structurally. DTIC

EFFECTS OF THRUST VECTOR CONTROL ON THE PERFORMANCE OF THE AEROBANG ORBITAL PLANE CHANGE MANEUVER M.S. Thesis
Richard E. Johnson Jun. 1993 76 p
(AD-A272532) Avail: CASI HC A05/MF A01

The aerobang maneuver, one of three types of aero-assisted orbital change methods, holds the possibility of reducing fuel consumption for orbital craft capable of atmospheric entry. It has been previously shown that different types of vehicles provide varying results over a constant heating rate trajectory. Further investigation into the optimization of the aerobang maneuver in this thesis includes the effects of using thrust vector control, the examination of the effects of increasing fuel mass fraction to increase orbital inclination changes, and the effects of that increase on both angle of attack and heating rate. The aerobang maneuver is shown to be capable of significant changes in orbital inclination in either a fixed heating rate or a fixed angle of attack mode for the Maneuverable Reentry Research Vehicle. LOW-COST UNMANNED AIR VEHICLE (UAV) FOR OCEANOGRAPHIC RESEARCH Final Report, Apr. - Oct. 1993
J. J. Kolle Nov. 1993 26 p
(Contract N00014-93-C-0029)
(AD-A273103) Avail: CASI HC A03/MF A01

This Phase 1 study has demonstrated the feasibility of developing a low-cost unmanned air vehicle (UAV) designed for a range of oceanographic research missions, including photogrammetry, radiometry, video imaging, and atmospheric profiling, at altitudes of up to 3 km and a range of 300 km. The work included identification of a data link, control system, autopilot, automated launcher, and recovery parachute. These subsystems will allow straightforward programming of a wide range of mission profiles and instrumentation control and accurate aircraft positioning (including differential GPS positioning within 10 km of a ground station). We also demonstrated a low-cost radio-controlled aircraft capable of carrying a 4-kg instrument payload and an autopilot that minimizes the skill (or control algorithm complexity) required to fly the aircraft. We have estimated that a complete UAV system, including the ground station and all avionics, can be sold commercially for under $35K. DTIC

DATA LINK DEVELOPMENT FOR THE ARCHYTAS VERTICAL TAKEOFF AND LANDING TRANSITIONAL FLIGHT UNMANNED AERIAL VEHICLE M.S. Thesis
Frederick W. Reichert, Jr. 17 Jun. 1993 94 p
(AD-A272499) Avail: CASI HC A05/MF A01

The development of a data link for the Archytas, a vertical takeoff and landing, transitional flight unmanned aerial vehicle (UAV) prototype being built by the Aeronautics Department at the Naval Postgraduate School, is chronicled. Archytas is intended to be a proof-of-concept platform to satisfy the Navy's real-time, over-the-horizon intelligence mission with a UAV that could be launched and recovered from a small combatant ship. A history of the Archytas command and control data link development, a full description of the data link as delivered for use on the prototype, principles for near term enhancements, and future considerations for the data link should the Archytas concept be adapted for use in an operational combat environment are provided. SURVEY OF LIFT-FAN AERODYNAMIC TECHNOLOGY
David H. Hickey and Jerry V. Kirk Sep. 1993 74 p
(NASA Order A-25364-D)
(NASA-CR-177615; A-93106; NAS 1.26:177615) Avail: CASI HC A04/MF A01

Representatives of NASA Ames Research Center asked that a summary of technology appropriate for lift-fan powered short takeoff/vertical landing (STOVL) aircraft be prepared so that new programs could more easily benefit from past research efforts. This paper represents one of six prepared for that purpose. The authors have conducted or supervised the conduct of research on lift-fan powered STOVL designs and some of their important components for decades. This paper will first address aerodynamic modeling requirements for experimental programs to assure realistic, trustworthy results. It will next summarize the results or efforts to develop satisfactory specialized STOVL components such as inlets and flow deflectors. It will also discuss problems with operation near the ground, aerodynamics while under lift-fan power, and aerodynamic prediction techniques. Finally, results of studies to reduce lift-fan noise will be presented. The paper will emphasize results from large scale experiments, where available, for reasons that will

be brought out in the discussion. Some work with lift-engine powered STOVL aircraft is also applicable to lift-fan technology and will be presented herein. Small-scale data will be used where necessary to fill gaps. Author

HANDBOOK. VOLUME 3: DIGITAL SYSTEMS VALIDATION BOOK PLAN Final Report
Joan Janowitz Jul. 1993 16 p
(Contract DTFA03-89-C-00043)
(DOT/FAA/CT-93/16-Vol-3) Avail: CASI HC A03/MF A01

The Digital Systems Validation Handbook is a tutorial series designed to provide certification engineers information on current topics related to digital avionics. The book plan lays the foundation for volume 3 of this series. The purpose of the handbook book plan is to identify technology and related issues that certification engineers are likely to encounter. Volume 3 of the handbook series will consist of approximately 20 chapters. Sixteen chapters are described in the book plan. Four were reserved for technologies or issues that might emerge during the course of the volume 3 life cycle. A list of potential handbook topics was derived from a survey of the literature, conference and seminar attendance, results of an informal questionnaire, and interviews with Federal Aviation Administration (FAA) National Resource Specialists, experts in the field of certification and digital avionics, National Aeronautics and Space Administration (NASA) officials, and persons in private industry. From this input, the list of potential topics was developed and refined into handbook chapters. In addition to the chapter list and descriptions, the handbook purpose, scope, and use is discussed. The unabridged list of topics is included in the book plan appendix. Author

HANDBOOK. VOLUME 2: DIGITAL SYSTEMS VALIDATION. CHAPTER 18: AVIONIC DATA BUS INTEGRATION TECHNOLOGY
D. Elwell, L. Harrison, J. Hensyl, and N. VanSuetendael Nov. 1993 179 p
(Contract DTFA03-86-C-00042)
(DOT/FAA/CT-88/10-Vol-2) Avail: CASI HC A09/MF A02

As multiple digital avionic systems were introduced into aircraft, there arose a need for digital communications between systems. In the early 1970s, many different digital data bus designs were used to provide this communication. Because these digital systems proved to be reliable and cost effective, their popularity increased. Proliferation led to standardization, particularly in the air transport category of aircraft, which allowed communications between line replaceable units (LRU's) to become more complex. The LRU's began to rely more heavily on each other to reduce the amount of equipment required. Sensor data and systems data could be shared among multiple systems, rather than each system requiring its own private source. Integrated digital avionics are increasingly being used to implement essential and critical functions that cannot be sufficiently reproduced by conventional means. The safety of such aircraft is highly dependent upon the computer software, hardware, and data buses connecting the systems. The newest concerns relate to the problems that are unique to highly integrated systems. There is no standard with which to assess the possible impact of these bus-based systems on aircraft safety. These and other advanced avionic systems will result in specific safety assessment problems when the appropriate data packages are submitted to the Federal Aviation Administration during the certification process. DESIGN OF A STATE-SPACE CONTROLLER FOR AN ADVANCED GAS TURBINE ENGINE
Karl F. Prigge 17 May 1993 50 p
(AD-A270859; USNA-TSPR-207) Avail: CASI HC A03/MF A01

A multi-input, multi-output (MIMO) controller for an advanced gas turbine has been developed and tested using a computer simulation. The engine modeled is a two-and-one-half spool gas turbine with both an intercooler and a regenerator. In addition, variable stator vanes are present in the free-power turbine. This advanced engine is proposed for future naval propulsion for both mechanical drive and electrical drive. The designed controller controls free-power turbine speed and turbine inlet temperature using fuel flow and angle of the stator vanes. The controller will also have four modes of operation to deal with over temperature and over speed conditions. An eight state reduced order controller was used with pole placement and LQR to arrive at control gains. Both these methods required considerable insight into the problem. This insight was provided by previous experience with controller design for a less complicated engine, and also by use of a polyhedral search model of the gas turbine engine. The difficulty with a MIMO controller was that both inputs affect both of the control variables. The classical resolution this problem is to have one

input control one variable at a fast time constant and the other input control the other variable at a slow time constant. The 'optimal' resolution of this problem is analyzed using the transient curves and basic control theory. DTIC

APPLICABILITY AND PERFORMANCE BENEFITS OF XD (TRADENAME) TITANIUM ALUMINIDES TO EXPENDABLE GAS TURBINE ENGINES Final Report, 1 Oct. 1991 - 31 Mar. 1993
Pamela Sadler, K. S. Kumar, and John A. Green Aug. 1993 168 p
(Contract DAAL04-91-C-0034)
(AD-A272998; MML-TR-93-09; ARL-CR-61) Avail: CASI HC A08/MF A02

The purpose of this program was to produce XD-TiAl compressor rotors for the experimental P9005 gas turbine engine to be used in the Army's Integrated High Performance Turbine Engine Technology program. Specific tasks included the casting of XD-titanium aluminide, processing optimization, component design analysis modifications and final component machining to specifications. Specifically, an ingot of a Ti-45Al-2Mn-2V alloy containing 7 volume % TiB2 was cast and then HIPed to eliminate residual porosity. Eight cylinders were machined from the HIPed material and isothermally forged. Microstructural analysis and mechanical property evaluation were performed on representative forgings. Several heat treatment schedules were examined, and the resulting microstructures were characterized using x-ray diffraction, optical and scanning electron microscopy. From these analyses, heat treatments were identified. Tensile behavior as a function of temperature, fracture toughness at room and elevated temperatures, creep resistance and fatigue response were evaluated. Fracture surfaces were characterized. Based on the observed mechanical properties, heat-treatment schedules were identified for the remaining forgings intended to be machined into final components. Williams International performed a detailed design analysis for the rotor. A local vendor was identified to machine the final component. DTIC

N94-21433# Naval Postgraduate School, Monterey, CA.
OPTIMIZATION AND PERFORMANCE ANALYSIS OF A SUPERSONIC CONICAL-FLOW WAVERIDER FOR A DECK-LAUNCHED INTERCEPT MISSION M.S. Thesis
David R. Price Jun. 1993 81 p
(AD-A272498) Avail: CASI HC A05/MF A01

An aircraft configuration for a deck launched intercept mission was investigated. The mission requirements for the carrier-launched and recovered aircraft included Mach 6 cruise out to a 1000 nautical mile combat radius and 20 minutes of combat followed by return to the carrier. A conical-flow waverider served as the starting point for the aircraft configuration. A hydrocarbon scramjet was integrated with the waverider body. The aft end of the waverider was faired to decrease the base area thereby reducing the transonic base drag. A numerical optimization was then completed to maximize the product of L/D (lift to drag ratio) and I(sub sp) (specific impulse). Variables for the optimization included the cone shock angle (used to derive the conical flow waverider) and the geometry of both the waverider body and the integrated propulsion system. The vehicle was constrained to a minimum volume of 3240 cubic feet, a maximum span of 60 feet and a fixed length of 60 feet. The integrated propulsion system was constrained to produce a minimum contraction ratio of 12.0 and assurance that the cowl shock was within an acceptable distance of the inlet shoulder of the combustor. The optimum configuration met or exceeded all constraints. L/D comparisons were made between the integrated configuration (i.e., the subject of this study), pure Mach 6 optimized waveriders and historical trends. DTIC

THRUST AUGMENTATION OPTIONS FOR THE BETA 2 TWO-STAGE-TO-ORBIT VEHICLE
Christopher A. Snyder Dec. 1993 17 p Presented at the AIAA Aircraft Design, Systems and Operations Meeting, Monterey, CA, 11-13 Aug. 1993; sponsored by AIAA
(RTOP 505-70-00)
(NASA-TM-106448; E-8301; NAS 1.15:106448; AIAA Paper 93-4014)
Avail: CASI HC A03/MF A01

NASA LeRC is continuing to study propulsion concepts for a horizontal takeoff and landing, fully reusable, two-stage-to-orbit vehicle. This will be capable of launching and returning a 10,000 pound payload to a 100 nautical mile polar orbit using low-risk technology. The vehicle, Beta 2, is a derivative of the USAF/Boeing Beta vehicle which was designed to deliver a 50,000 pound payload to a similar orbit. Beta 2 stages at Mach 6.5 and about 100,000 ft altitude. The propulsion system for the booster is an over/under turbine bypass engine/ramjet configuration. In this paper, several options for thrust augmentation were studied in order to improve the performance of this engine where there was a critical need. Options studies were turbine engine overspeed in the transonic region, water injection at a various turbine engine locations also during the transonic region, and water injection at the turbine engine face during high speed operation. The methodology, constraints, propulsion performance, and mission study results are presented. Author (revised)

An experimental and computational study is reported for the flow of a turbulent jet discharging into a rectangular enclosure. The experimental configurations consisting of primary jets only, annular jets only, and a combination of annular and primary jets are investigated to provide a better understanding of the flow field in an annular combustor. A laser Doppler velocimeter is used to measure mean velocity and Reynolds stress components. Major features of the flow field include recirculation, primary and annular jet interaction, and high turbulence. A significant result from this study is the effect the primary jets have on the flow field. The primary jets are seen to create statistically larger recirculation zones and higher turbulence levels. In addition, a technique called marker nephelometry is used to provide mean concentration values in the model combustor. Computations are performed using three levels of turbulence closures, namely k-epsilon model, algebraic second moment (ASM), and differential second moment (DSM) closure. Two different numerical schemes are applied. One is the lower-order power-law differencing scheme (PLDS) and the other is the higher-order flux-spline differencing scheme (FSDS). A comparison is made of the performance of these schemes. The numerical results are compared with experimental data. For the cases considered in this study, the FSDS is more accurate than the PLDS. For a prescribed accuracy, the flux-spline scheme requires a far fewer number of grid points. Thus, it has the potential for providing a numerical error-free solution, especially for three-dimensional flows, without requiring an excessively fine grid. Although qualitatively good comparison with data was obtained, the deficiencies regarding the modeled dissipation rate (epsilon) equation, pressure-strain correlation model, and the inlet epsilon profile and other critical closure issues need to be resolved before one can achieve the degree of accuracy required to analytically design combustion systems. BLADE ROW INTERACTION EFFECTS ON FLUTTER AND FORCED RESPONSE

Daniel H. Buffum Dec. 1993 19 p Presented at the 29th Joint Propulsion Conference, Monterey, CA, 28 Jun. - 1 Jul. 1993; cosponsored by AIAA, SAE, ASME, and ASEE See also A93-49911

Avail: CASI HC A03/MF A01

In the flutter or forced response analysis of a turbomachine blade row, the blade row in question is commonly treated as if it is isolated from the neigboring blade rows. Disturbances created by vibrating blades are then free to propagate away from this blade row without being disturbed. In reality, neighboring blade rows will reflect some portion of this wave energy back toward the vibrating blades, causing additional unsteady forces on them. It is of fundamental importance to determine whether or not these reflected waves can have a significant effect on the aeroelastic stability or forced response of a blade row. Therefore, a procedure to calculate intra-blade-row unsteady aerodynamic interactions was developed which relies upon results available from isolated blade row unsteady aerodynamic analyses. In addition, an unsteady aerodynamic influence coefficient technique is used to obtain a model for the vibratory response in which the neighboring blade rows are also flexible. The flutter analysis shows that interaction effects can be destabilizing, and the forced response analysis shows that interaction effects can result in a significant increase in the resonant response of a blade row. Avail: CASI HC A03/MF A01; 4 functional color pages

A production 3-D elliptic flow code has been used to calculate non-reacting and reacting flow fields in an experimental mixing section relevant to a rich burn/quick mix/lean burn (RQL) combustion system. A number of test cases have been run to assess the effects of the variation in the number of orifices, mass flow ratio, and rich-zone equivalence ratio on the flow field and mixing rates. The calculated normalized temperature profiles for the non-reacting flow field agree qualitatively well with the normalized conserved variable isopleths for the reacting flow field indicating that non-reacting mixing experiments are appropriate for screening and ranking potential rapid mixing concepts. For a given set of jet momentum-flux ratio, mass flow ratio, and density ratio (J, MR, and DR), the reacting flow calculations show a reduced level of mixing compared to the non-reacting cases. In addition, the rich-zone equivalence ratio has noticeable effect on the mixing flow characteristics for reacting flows. Author (revised)

OPTIONS FOR THRUST AUGMENTATION FOR THE BETA 2 TWO-STAGE-TO-ORBIT LAUNCH VEHICLE

Kenol Jules Dec. 1993 15 p

(RTOP 505-70-00)

(NASA-TM-106418; E-8255; NAS 1.15:106418) Avail: CASI HC A03/MF A01

A study to improve the performance of the NASA two-stage-to-orbit vehicle was undertaken. The NASA concept, a horizontal takeoff and landing, fully reusable, two-stage to orbit vehicle, will be capable of launching and returning a 10,000 pound payload to a 100 nmi polar orbit. The vehicle, Beta 2, is a derivative of the USAF/Boeing Beta vehicle which was designed to deliver a 50,000 pound payload to a similar orbit. Beta 2 stages at Mach 6.5 and about 100,000 feet altitude. The propulsion system for the booster is an over/under turbine engine/ramjet configuration. In this paper a study was performed for one of the candidate engines, the variable cycle engine, to assess its potential to meet the required performance needs of the Beta 2 vehicle. Several options for thrust augmentation were studied in order to improve the performance of the engine where there was a critical need. The methodology, constraints, propulsion performance, and mission study results are presented. Author (revised)

ON THE ESTIMATION ALGORITHM USED IN ADAPTIVE PERFORMANCE OPTIMIZATION OF TURBOFAN ENGINES

Martin D. Espana and Glenn B. Gilyard Dec. 1993 34 p Presented at the AIAA Joint Propulsion Conference, Monterey, CA, 28 Jun. - 1 Jul. 1993 See also A93-49710

(RTOP 533-02-39)

(NASA-TM-4551; H-1908; NAS 1.15:4551; AIAA Paper 93-1823) Avail: CASI HC A03/MF A01

The performance seeking control algorithm is designed to continuously optimize the performance of propulsion systems. The performance seeking control algorithm uses a nominal model of the propulsion system and estimates, in flight, the engine deviation parameters characterizing the engine deviations with respect to nominal conditions. In practice, because of measurement biases and/or model uncertainties, the estimated engine deviation parameters may not reflect the engine's actual off-nominal condition. This factor has a necessary impact on the overall performance seeking control scheme exacerbated by the open-loop character of the algorithm. The effects produced by unknown measurement biases over the estimation algorithm are evaluated. This evaluation allows for identification of the most critical measurements for application of the performance seeking control algorithm to an F100 engine. An equivalence relation between the biases and engine deviation parameters stems from an observability study; therefore, it is undecided whether the estimated engine deviation parameters represent the actual engine deviation or whether they simply reflect the measurement biases. A new algorithm, based on the engine's (steady-state) optimization model, is proposed and tested with flight data. When compared with previous Kalman filter schemes, based on local engine dynamic models, the new algorithm is easier to design and tune and it reduces the computational burden of the onboard computer. FSR BASED FORCE TORQUE TRANSDUCER DESIGN M.S. Thesis

Charles A. Gunzel, III Jun. 1993 135 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A271337) Avail: CASI HC A07

This thesis report discusses the design, construction and calibration of two force-torque transducers for use in a force control override of a rate control system. Pre-loaded force sensing resistors were used in a computer model to determine the number and location of sensors necessary to resolve three forces and three moments. An analysis was conducted on this full order model to determine redundancy limits. A reduced order model was then used to determine the sensor configuration required to resolve three forces and only one moment. Prototypes of the reduced order model were then built in two different sizes, and used to sense and display applied forces and moments. DTIC

APPARATUS AND METHOD FOR IMPROVING SPIN RECOVERY ON AIRCRAFT Patent

H. Paul Stough, II, inventor (to NASA) 2 Nov. 1993 9 p Filed 21 Sep. 1992 Supersedes N93-20039 (31 - 7, p 1786)

(NASA-Case-LAR-14747-1; US-Patent-5,259,573;

US-Patent-Appl-SN-948057; US-Patent-Class-244-75R;

US-Patent-Class-244-87; Int-Patent-Class-B64C-9/02) Avail: US Patent and Trademark Office

Previous research on airplane spinning and recovery has shown that at potential spin conditions (high angles of attack with rotation) the horizontal tail, depending upon its location, can create a wake about the vertical tail and rudder which can adversely affect airplane spin and recovery characteristics. Many methods of altering the tail geometry to modify these interference effects were investigated for improving airplane spin and recovery characteristics. Examples of changes includes relocation of the horizontal tail, increasing control surface travel, and use of a 'flip tail' that can be rotated to extreme angles for spin recovery. A device is provided which improves the spin recovery characteristics of aircraft which involves attaching the horizontal tail of the aircraft to the aircraft such that a gap remains between the root end of each horizontal tail section and the fuselage or vertical tail of the aircraft. The gaps measure between about 15 and 30 percent of the tail semispan. The gaps may be covered by shields which are released should a spin occur.

OPTIMAL FLIGHT GUIDANCE FOR AIRCRAFT IN WINDSHEAR Patent

Terry L. Zweifel, inventor (to Honeywell, Inc.) and J. Rene Barrios, inventor (to Honeywell, Inc.) 15 Sep. 1992 28 p Filed 8 Dec. 1987

(CA-Patent-1,307,573; Int-Patent-Class-B64C-13/16; CTN-93-60686)

Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

An apparatus is provided for controlling the vertical flight path of an aircraft encountering a windshear condition. The apparatus provides guidance commands to optimize the resultant flight path of the aircraft and maximize time in the air and distance travelled. When operating in the presence of a tail windshear, a fixed flight path angle independent of the windshear magnitude is commanded that minimizes excitation of the aircraft's phugoid oscillatory mode while maintaining adequate clearance of hills and buildings that may be present around the airport. In the presence of a vertical wind component, the effect on the aircraft's flight path angle is computed and added to the fixed flight path angle command. The guidance command is limited in magnitude to preclude commands which would cause the aircraft to exceed the maximum allowable angle of attack. An angle of attack sensor provides a signal which is combined with a sensed pitch angle to derive a signal corresponding to the actual flight path angle. A command signal corresponding to a fixed flight path angle at a predetermined elevation is combined with a signal corresponding to the effective change in flight path angles due to a vertical windshear component and with the actual flight path angle to derive the pitch command signal. A COMPARATIVE ROBUSTNESS EVALUATION OF FEEDFORWARD NEUROFILTERS

Terry Troudet (Sverdrup Technology, Inc., Brook Park, OH.) and Walter Merrill Dec. 1993 11 p Proposed for presentation at the 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA

(Contract NAS3-25266; RTOP 584-03-11)

(NASA-TM-106440; E-8282; NAS 1.15:106440; AIAA Paper 94-0397)

Avail: CASI HC A03/MF A01

A comparative performance and robustness analysis is provided for feedforward neurofilters trained with back propagation to filter additive white noise. The signals used in this analysis are simulated pitch rate responses to typical pilot command inputs for a modern fighter aircraft model. Various configurations of nonlinear and linear neurofilters are trained to estimate exact signal values from input sequences of noisy sampled signal values. In this application, nonlinear neurofiltering is found to be more efficient than linear neurofiltering in removing the noise from responses of the nominal vehicle model, whereas linear neurofiltering is found to be more robust in the presence of changes in the vehicle dynamics. The possibility of enhancing neurofiltering through hybrid architectures based on linear and nonlinear neuroprocessing is therefore suggested as a way of taking advantage of the robustness of linear neurofiltering, while maintaining the nominal performance advantage of nonlinear neurofiltering.

STRUCTURAL MODELING: AN APPLICATION FRAMEWORK AND DEVELOPMENT PROCESS FOR FLIGHT SIMULATORS Final Report

Gregory D. Abowd, Len Bass, Larry Howard, and Linda Northrop Aug. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F19628-90-C-0003)

(AD-A271348; CMU/SEI-93-TR-14; ESC-TR-93-192) Avail: CASI HC A03

In this paper, we present the structural modeling approach, an application framework and development process for the construction of flight simulators. Structural modeling was developed to address functional, nonfunctional, and process requirements for flight simulators. It has been successfully used in the development of large scale (one million lines of Ada code) flight simulators for the United States Air Force. A structural model promotes a simple and coherent software architecture with a small number of specialized structural elements obeying a few system-wide coordination

strategies. It is this simplicity coherence of the software architecture that enables analysis to demonstrate the quality of the system. DTIC

THE AEROGEL MESH CONTAMINATION COLLECTOR Final Report, Oct. 1991 - Sep. 1992
Steven P. Hotaling Jul. 1993 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A270537; RL-TR-93-148) Avail: CASI HC A05

High performance optical and microelectronic components have ever tightening contamination specifications placed upon them. Contamination is now seen as a major reason for the degradation of space based optical systems and failure of high density integrated circuits used throughout industrial and military systems. To address this problem, contamination removal and collection techniques have been developed by Rome Laboratory (RL). However, some of these removal techniques create a flux of removed contaminants, which then may re-deposit on clean surfaces or be ejected into the environment. Current collection devices such as filters, charged metal plates or screens, and charged dielectric have collection efficiencies and capture radii incommensurate with the new nano-scale semiconductor devices and space optics system cleanliness requirements. Presented here is a new contamination collector (patent pending). The collector (Aerogel Mesh Contamination Collector) or AMCC, collects and contains particulate and molecular contaminants either passively or used in conjunction with contamination removal devices creating a synergistic contamination control system with prevention, removal, and collection capabilities. The system is applicable to both clean room and cryogenic-vacuum conditions such as spacecraft environments. DTIC

A FULL-COLOR, HIGH-RESOLUTION LASER PROJECTOR FOR A FLIGHT SIMULATOR VISUAL DISPLAY Final Report, Jan. - Jul. 1993
Philipp W. Peppler and J. C. Gainer Aug. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 1123)
(AD-A270578; AL/HR-TR-1993-0120) Avail: CASI HC A03

Laser projection is a promising approach to solving many of the shortcomings associated with current flight simulator projection methods. The advantages of laser projection were investigated and are discussed. The characteristics of light valve, cathode-ray tube (CRT), liquid crystal display (LCD), and laser projectors are compared. It was found that laser projection offers many benefits over current projection technology. Laser projection promises an increased color gamut, higher luminance, zero persistence, and increased line rate. The technology required to develop an efficient, cost-effective laser projector was researched and is described. Recent advances in laser diodes, solid-state diodes, and other rapidly developing technologies and techniques promise new territory for laser projection. It is concluded that laser projection is a promising solution to the shortcomings of flight simulator visual displays and that the technology now exists to develop an efficient, cost effective laser projector. NOTES ON ANTARCTIC AVIATION
Malcolm Mellor Aug. 1993 154 p
(AD-A273018; CRREL-93-14) Avail: CASI HC A08/MF A02

Antarctic aviation has been evolving for the best part of a century, with regular air operations developing over the past three or four decades. Antarctica is the last continent where aviation still depends almost entirely on expeditionary airfields and 'bush flying', but change seems imminent. This report describes the history of aviation in Antarctica, the types and characteristics of existing and proposed airfield facilities, and the characteristics of aircraft suitable for Antarctic use. It now seems possible for Antarctic aviation to become an extension of mainstream international aviation. The basic requirement is a well-distributed network of hard-surface airfields that can be used safely by conventional aircraft, together with good international collaboration. The technical capabilities already exist. DTIC

An assessment of a novel Optical Pressure Measurement System (OPMS) made in a high speed wind tunnel is reported. A model of a cropped delta wing was made available to demonstrate and assess OPMS. For this purpose pressure distributions were measured separately as well as simultaneously with both OPMS and a conventional technique via pressure taps for comparisons. Temperature variations on the model surface were determined by means of an infrared camera and thermocouples in order to assess a possible error caused by temperature changes. Surface oil flow visualizations were performed in order to get additional information on boundary layer transition, separation and reattachment lines as well as vortex positions. ESA

PASSENGER TERMINAL LEVEL OF SERVICE MEASUREMENT: A UTILITY THEORETIC APPROACH M.S. Thesis
Khizer Farooq Omer May 1990 317 p
(ISBN-0-315-59037-8; CTN-94-60885) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The relationship between the existing space/service standards of various processors of an airport system is investigated, along with the user-perceived values of these space/service standards. The various processors include check-in, baggage claim, boarding lounge, and preliminary inspection line. The utility of these standards and the level of service of various airport subsystems are formulated. A utility theoretic approach is used to measure the airport landside level of service. Attitudinal surveys of airport users were conducted at Ottawa and Toronto international airports. For the airport processors mentioned above, the selected performance measures were studied to arrive at the individual as well as composite utility of those processors. Equations for the utility functions of those processors have been calculated and their application in developing airport landside level of service standards is discussed. The use of these individual and composite utility functions for each processor is described and recommendations are made for further research. Author (CISTI)

AN AIRPORT ECONOMIC IMPACT STUDY PROCEDURE FOR ATLANTIC CANADA M.S. Thesis
Terry Mark Mazerolle Aug. 1990 138 p
(ISBN-0-315-59445-4; CTN-94-60886) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A methodology was developed for economic impact studies suitable for the size of airport and economic conditions extant in Atlantic Canada. The methodology enables quantification of the net economic impact of an airport on the surrounding economy as an employer and as a consumer of goods and services. Three levels of airport dependent impacts were defined. Direct impacts are those economic activities derived from airport dependent

firms and from operation of the airport. Indirect impacts are the effect of the expenditures of airport dependent firms and the subsequent rounds of spending which occur in the local economy as a result. Induced impacts measure the effect of the wages of those employed by airport dependent firms. The airport's total impact is the sum of the direct, indirect, and induced impacts. The methodology of data collection described was explored with a case study at Fredericton Airport. The results showed that the airport is a far more valuable economic resource than was commonly perceived. It is concluded that a unique methodology was necessary to measure accurately the economic impact of an airport in the Atlantic region of Canada. Author (CISTI)

A high-level computer program called TERMSIM has been developed to simulate passenger terminal operation in terms of number of passengers arriving, being served, and queueing at the various terminal facilities. It is assumed that passenger movements may be represented as a fluid flowing through a system of interconnected reservoirs corresponding to terminal components. Paxgraphs, functions describing passenger arrivals as a function of time before flight departure or after flight arrival, are used to generate passenger flows for user-defined discrete time intervals. The simulation analyzes passenger movement through the predetermined paths within the terminal. Operation of the terminal facilities is simulated by calculating output flows and queue lengths given input flows, queue lengths, and service characteristics at the end of discrete time intervals. Seven preprogrammed models have been developed to simulate terminal components, the passenger greeter and bag matching processes, and departure concourse and ancillary facilities. The capabilities of TERMSIM are demonstrated through a simulation of a typical day at Toronto International Airport, and results are shown to be similar to those produced by the Transport Canada simulation model. A guide to the use of TERMSIM is included. Author (CISTI)

A STUDY OF PARALLEL PIER FINGER AIRPORT TERMINAL CONFIGURATION M.S. Thesis
Ezekiel Sunday Dada Dec. 1992 167 p
(ISBN-0-315-83128-6; CTN-94-60936) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Taxiing, walking, baggage transport, and airport construction were studied to determine their effect on the geometry of pier finger terminals. The best terminal geometry based on taxiing alone is one with shorter fingers in the middle and longer ones at the ends. On the other hand, geometry that minimizes baggage transportation distance is the one with the longest pier at the center. Baggage transportation distance is affected both by the geometry of the terminal and the sorting room strategy adopted. Decentralized sorting gives a lower baggage tractor distance than centralized sorting. Walking distance has been studied extensively by others who found that pier finger terminals minimize walking. As far as the operations considered are concerned, the terminal with pier lengths decreasing with distance from the center gives the best combined optimal geometry. It also gives a lower number of piers than that found by others for walking only. Author (CISTI)

A NEW PROCEDURE FOR ORBIT DETERMINATION BASED ON THREE LINES OF SIGHT: ANGLES ONLY Technical Report
R. H. Gooding Apr. 1993 66 p
(AD-A272937; DRA-TR-93004) Avail: CASI HC A04/MF A01

A new procedure has been developed for the general solution of the minimal angles-only problem in which an orbit is determined from three line-of-sight observations. The basis of the approach is a higher-order Newton correction of the assumed values for two of the unknown ranges, appeal being made to the author's (published) universal solution of Lambert's orbital boundary-value problem. The new procedure is free of the inherent limitations of the traditional methods of Laplace and Gauss, these methods being outlined in a summary of previous approaches to this classical problem. In particular, the observations are permitted to span several revolutions when the orbit is elliptic; multiple solutions can be obtained; and there is no restriction on the configuration of the three observing sites. The procedure has been carefully tested, some of the examples being taken from the literature. A number of test problems have been solved that would have failed by existing methods. DTIC

Apparatus for simulating an exoatmospheric structure, such as a spin stabilized satellite, in an environment subject to gravitational forces is presented. The apparatus includes a floating structure which is pivotally and rotationally supported upon a gimballed bearing structure positioned adjacent to the center of mass of the floating structure and suspended upon a support structure. The floating structure is translatable in either vertical direction relative to the supporting structure upon a vertically movable suspension system connected to the supporting structure. The supporting structure is provided with bearing assemblies which are adapted to engage a supporting surface for permitting freedom of movement of the supporting structure over the supporting structure in any direction.

SYSTEM IDENTIFICATION OF THE DAISY LARGE SPACE STRUCTURE EMULATOR M.S. Thesis
Roberto Guccione 1992 138 p
(ISBN-0-315-83533-8; CTN-94-60950) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The Daisy structure consists of a central, gimbal-mounted hub and ten counterbalanced ribs interconnected with spring struts. All spring/inertia elements have been carefully sized so that Daisy exhibits the desired low natural frequencies and damping, and clustered modes of vibration, typical of large space structures. The eigensystem realization algorithm (ERA) is introduced to realize a mathematical model representative of the elastic vibrational modes of Daisy. The theory behind discrete state space systems, Markov parameters, and the ERA are presented, along with the implementation of the theory and the signal processing that was needed. Example systems and results are described to illustrate some of the characteristics of the realization algorithm, as well as the phenomenon of mode localization often encountered in closed periodic structures such as Daisy. The system natural frequencies, damping ratios, and mode shapes are identified for five-rib and ten-rib free cases, with the hub locked. A state space realization is investigated for a two-rib free case.

TOTAL SYSTEMS DESIGN ANALYSIS OF HIGH PERFORMANCE STRUCTURES
V. Verderaime Washington Nov. 1993 65 p
(NASA-TP-3432; M-733; NAS 1.60:3432) Avail: CASI HC A04/MF A01

Designer-control parameters were identified at interdiscipline interfaces to optimize structural systems performance and downstream development and operations with reliability and least life-cycle cost. Interface tasks and iterations are tracked through a matrix of performance disciplines integration versus manufacturing, verification, and operations interactions for a total system design analysis. Performance integration tasks include shapes, sizes, environments, and materials. Integrity integrating tasks are reliability and recurring structural costs. Significant interface designer control parameters were noted as shapes, dimensions, probability range factors, and cost. Structural failure concept is presented, and first-order reliability and deterministic methods, benefits, and limitations are discussed. A deterministic reliability technique combining benefits of both is proposed for static structures which is also timely and economically verifiable. Though launch vehicle environments were primarily considered, the system design process is applicable to any surface system using its own unique filed environments.

SPACE SHUTTLE MISSION STS-61: HUBBLE SPACE TELESCOPE SERVICING MISSION-01 Press Kit
Dec. 1993 53 p
(NASA-TM-109344; NAS 1.15:109344) Avail: CASI HC A04/MF A01

This press kit for the December 1993 flight of Endeavour on Space

Shuttle Mission STS-61 includes a general release, cargo bay payloads and activities, in-cabin payloads, and STS-61 crew biographies. This flight will see the first in a series of planned visits to the orbiting Hubble Space Telescope (HST). The first HST servicing mission has three primary objectives: restoring the planned scientific capabilities, restoring reliability of HST systems and validating the HST on-orbit servicing concept. These objectives will be accomplished in a variety of tasks performed by the astronauts in Endeavour's cargo bay. The primary servicing task list is topped by the replacement of the spacecraft's solar arrays. The spherical aberration of the primary mirror will be compensated by the installation of the Wide Field/Planetary Camera-II and the Corrective Optics Space Telescope Axial Replacement. New gyroscopes will also be installed along with fuse plugs and electronic units. Derived from text

A retainer member suitable for retaining a gap filler placed in gaps between adjacent tile members is presented. One edge of the retainer member may be attached to the gap filler and another edge may be provided with a plurality of tab members which in an intermediate position do not interfere with placement or removal of the gap filler between tile members. The retainer member may be fabricated from a shape memory alloy which when heated to a specified memory temperature will thermally activate the tab members to predetermined memory positions engaging the tile members to retain the gap filler in the gap. This invention has particular application to the thermal tiles on space vehicles such as the Space Shuttle Orbiter.

NEP EARLY FLIGHT PROGRAM: SYSTEM PERFORMANCE AND DEVELOPMENT CONSIDERATIONS

Michael P. Doherty and Jeffrey A. George Dec. 1993 9 p Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA, DGLR, AIDAA, and JSASS Sponsored by NASA. Washington

(RTOP 506-49-00)

(NASA-TM-106415; IEPC-93-064; E-8252; NAS 1.15:106415) Avail: CASI HC A02/MF A01

A mission/system study of Nuclear Electric Propulsion (NEP) for early robotic planetary science mission applications has been conducted. Subject missions considered included a Mars orbiter with a Phobos and Deimos Rendezvous; a Comet Kopff Rendezvous; a Multiple Mainbelt Asteroid Rendezvous (MMBAR); an Asteroid (Vesta) Sample Return; a Trojan Asteroid (Odysseus) Rendezvous; and a Jupiter mini Grand Tour. The purpose of the study was to determine if 'near-term' NEP technology could be used on an early NEP flight to demonstrate the technologies while conducting a useful science mission. The analysis shows that, depending upon technology readiness date, the missions could be performed with low power NEP. The technology and system development costs associated with vehicle/stage development for a candidate mission are presented. The study assumed relatively mature space electric power and space electric propulsion technologies (more advanced technologies have been already shown by others to be enabling for many outer planetary missions). Thus, a very important first step in using NEP would be taken, which would contribute valuable solar system science, as well as reduce the risks associated with using NEP for more demanding outer planetary science mission applications. THE 1992 SEALS FLOW CODE DEVELOPMENT WORKSHOP

Anita D. Liang and Robert C. Hendricks Oct. 1993 278 p Workshop held in Cleveland, OH, 5-6 Aug. 1992

(Contract NAS3-25644; RTOP 590-21-11)

(NASA-CP-10124; E-8172; NAS 1.55:10124) Avail: CASI HC A13/MF A03

A two-day meeting was conducted at the NASA Lewis Research Center on August 5 and 6, 1992, to inform the technical community of the progress of NASA Contract NAS3-26544. This contract was established in 1990 to develop industrial and CFD codes for the design and analysis of seals. Codes were demonstrated and disseminated to the user community for evaluation. The peer review panel which was formed in 1991 provided recommendations on this effort. The technical community presented results of their activities in the area of seals, with particular emphasis on brush seal systems. For individual titles, see N94-21791 through N94-21797.

BRUSH SEAL BRISTLE FLEXURE AND HARD-RUB CHARACTERISTICS c37

Robert C. Hendricks, Julie A. Carlile, and Anita D. Liang *In its* The 1992 Seals Flow Code Development Workshop Oct. 1993 p 95-115 (For primary document see N94-21790 05-16)

Avail: CASI HC A03/MF A03

The bristles of a 38.1-mm (1.5-in.) diameter brush seal were flexed by a tapered, 40-tooth rotor operating at 2600 rpm that provided sharp leading-edge impact of the bristles with hard rubbing of the rotor lands. Three separate tests were run with the same brush accumulating over 1.3 x 10(exp 9) flexure cycles while deteriorating 0.2 mm (0.008 in.) radially. In each, the test bristle incursion depth varied from 0.130 to 0.025 mm (0.005 to 0.001 in.) or less (start to stop), and in the third test the rotor was set 0.25 mm (0.010 in.) eccentric. Runout varied from 0.025 to 0.076 mm (0.001 to 0.003 in.) radially. The bristles wore but did not pull out, fracture, or fragment. Bristle and rotor wear debris were deposited as very fine, nearly amorphous, highly porous materials at the rotor groove leading edges and within the rotor grooves. The land leading edges showed irregular wear and the beginning of a convergent groove that exhibited sharp, detailed wear at the land trailing edges. Surface grooving, burnishing, 'whipping', and hot spots and streaks were found. With a smooth-plug rotor, post-test leakage increased 30 percent over pretest leakage. Author

INTEGRITY TESTING OF BRUSH SEAL IN A T-700 ENGINE c37

Robert C. Hendricks, Thomas A. Griffin, George A. Bobula, Robert C. Bill, and Harold W. Howe (Technetics, Inc., DeLand, FL.) *In its* The 1992 Seals Flow Code Development Workshop Oct. 1993 p 117-138 (For primary document see N94-21790 05-16)

Avail: CASI HC A03/MF A03

A split-ring brush seal was fabricated, installed between two labyrinth-honeycomb shroud seals, and tested in the fourth-stage turbine of a T-700 engine. The annealed Haynes 25 bristles rubbed directly against the nonconditioned, irregular Rene 80 turbine blade shroud surface. A total of 21 hr of cyclic and steady-state data were taken with surface speeds of 335 m/s (1100 ft/s) and shroud temperatures to 620 C (1150 F). Wear

appeared to be rapid initially, with an orange flash of hot brush fragments during the first engine startup, to minimal after 10 hr of operation. The brush survived the testing but experienced some bristle pullouts and severe bristle wear; some turbine interface wear and possible material transfer was noted. Future design concerns center on tribological behavior at the interface with or without lubricants. Author

AIR FORCE BRUSH SEAL PROGRAMS **c37**

Connie Dowler *In* NASA. Lewis Research Center, The 1992 Seals Flow Code Development Workshop Oct. 1993 p 149-156 (For primary document see N94-21790 05-16)

Avail: CASI HC A02/MF A03

Aggressive pursuit of increased performance in gas turbine engines is driving the thermodynamic cycle to higher pressure ratios, bypass ratios, and turbine inlet temperatures. As these parameters increase, internal air system and resultant thermodynamic cycle losses increase. This conflict of reducing internal airflows while increasing thermodynamic efficiency and performance is putting more emphasis on improvements to the internal flow system. One improvement that has been and continues to be pursued by the Air Force for both man-rated and expendable turbine engine applications is the brush seal. This presentation briefly describes both past and current brush seal research and development programs and gives a summary of demonstrator and developmental engine testing of brush seals. Author

NAVY GTE SEAL DEVELOPMENT ACTIVITY **c37**

Carl P. Grala *In* NASA. Lewis Research Center, The 1992 Seals Flow Code Development Workshop Oct. 1993 p 157-165 (For primary document see N94-21790 05-16)

Avail: CASI HC A02/MF A03

Under the auspices of the Integrated High Performance Turbine Engine Technology Initiative, the Naval Air Warfare Center conducts advanced development programs for demonstration in the next generation of air-breathing propulsion systems. Among the target technologies are gas path and lube oil seals. Two development efforts currently being managed by NAWCAD are the High Performance Compressor Discharge Film-Riding Face Seal and the Subsonic Core High Speed Air/Oil Seal. The High Performance Compressor Discharge Film-Riding Face Seal Program aims at reducing parasitic leakage through application of a film-riding face sea concept to the compressor discharge location of a Phase 2 IHPTET engine. An order-of-magnitude leakage reduction relative to current labyrinth seal configurations is expected. Performance goals for these seals are (1) 1200 F air temperature, (2) 800 feet-per-second surface velocity, and (3) 600 SPI differential pressure. The two designs chosen for fabrication and rig test are a spiral groove and a Rayleigh step seal. Rig testing is currently underway. The Subsonic Core High Speed Air/Oil Seal Program is developing shaft-to-ground seals for next-generation propulsion systems that will minimize leakage and provide full life. Significantly higher rotor speeds and temperatures will be experienced. Technologies being exploited include, hydrodynamic lift assist features, ultra light weight designs, and improved cooling schemes. Parametric testing has been completed; a final seal design is entering the endurance test phase. Author

COMPLIANT SEAL DEVELOPMENT **c37**

Robert C. Hendricks *In its* The 1992 Seals Flow Code Development Workshop Oct. 1993 p 171-173 (For primary document see N94-21790 05-16)

Avail: CASI HC A01/MF A03

The compliant metallic seal combines the noncontact feature of the labyrinth seal, the low leakage of a mechanical seal, and the compliant nature of the brush seal. It consists of several thin metallic elements or leaves mounted within a ring which is press fit into the housing, and in form, sort of resembles a lip seal sections wiping the shaft. A second set of overlapping cover leaves are placed on top of the shaft riding leaves which reduces leakage and provides stiffness. The leaves can be straight or angle cut. The shaft riding fingers are designed with mismatched curvature to provide lift off similar to the Rayleigh lift pads in mechanical seals with leading edge clearances nearly twice those of the trailing edge as as shown by Fleming to be optimal for gas flows in convergent seal passages. Leading edge clearances range from 300 to 500 microinches. Balance pockets beneath the leaves provide fluid film feed to the 'Rayleigh lift' surface and the proper balance ratio (mechanical seal) when combined with the static pressure and film pressure. The leaves flex in the radial direction and accommodate thermomechanical behavior as well as axial motion and angular misalignment. In the static mode, there is a net closing force on the leaves. The seals were tested to 70 psi at speeds to 16,000 rpm or surface speeds to 330 fps and temperatures from ambient to 440 F. A slow cycle through the rig critical at 10,000 rpm induced a radial vibration response of 0.004 to 0.005 inch were accommodated by the seal. Preliminary performance data are encouraging demonstrating hydrodynamic liftoff and noncontacting operation at pressure and speeds typical of gas turbine engines. The leakage performance data are significantly better than commercial labyrinth and brush seals which should be expected as this design incorporates the features of the low leakage face or mechanical seal along with the flexibility of the brush configuration. DYNAMICS OF FACE SEALS FOR HIGH SPEED TURBOMACHINERY **c37**

Simon Leefe *In* NASA. Lewis Research Center, The 1992 Seals Flow Code Development Workshop Oct. 1993 p 197-210 (For primary document see N94-21790 05-16)

Avail: CASI HC A03/MF A03

Face seals in rocket engine fuel and oxidizer turbopumps have been the subject of intense investigation for over 25 years. While advances have been made in the understanding of thin film lubrication between seal faces, valuable data has been produced on the friction and wear of material pairs in cryogenic environments; pioneering work has been done on the effect of lubricant phase change in seals, and many improvements have been made in mechanical seal design. Relatively superficial attention has been given to the vibrational dynamics of face seals in high-speed turbomachinery. BHR Group Ltd. (formerly BHRA) has recently completed the first stage of a study, commissioned by the European Space Agency, to investigate this area. This has involved the development of a two-dimensional adiabatic, turbulent lubrication model for thick gas film applications, the production of an integrated mathematical model of gas seal vibrational dynamics for thin film applications, implementation in software, the undertaking of an experimental program to validate software against variations in operating conditions and design variables, and suggestions for improved seal design. MODELING BRISTLE LIFT-OFF IN IDEALIZED BRUSH SEAL CONFIGURATIONS **c37**

Vijay Modi *In* NASA. Lewis Research Center, The 1992 Seals Flow Code Development Workshop Oct. 1993 p 217-232 (For primary document see N94-21790 05-16)

Avail: CASI HC A03/MF A03

We attempt in this paper to develop a model for the flow through brush seals and determine their elastic behavior in order to predict the dependence of brush/journal clearance on geometry and operating conditions. Several idealizations regarding brush seal configuration, flow conditions, and elastic behavior are made in the analysis in order to determine closed form parametric dependence. This formulation assumes that there is no initial interference between the bristle tip and the rotor. Also, interbristle, bristle-backing plate, and bristle-rotor friction is neglected. The bristle bundle or the brush seal as it is alternately called is assumed homogeneous and isotropic on a macroscopic scale so that a physical property like permeability is uniform. The fluid is assumed to be homogeneous, incompressible, viscous, and flowing under steady conditions. A schematic of a brush seal is shown. If the nominal bristle-shaft interference is absent then under static conditions the bristles may deflect axially due to the imposed pressure differential. This axial deflection may create a clearance permitting leakage flow in excess of that which occurs through the porous matrix formed by the bristle bundles. Under dynamic conditions the Couette flow created by shaft motion could be strong enough to

cause bristle deflection and once again a clearance may develop. The paper proposes a means to determine this clearance (or at least describe its parametric dependence on geometry and operating conditions) under static as well as dynamic conditions. Derived from text

SPECIALIZED DATA ANALYSIS FOR THE SPACE SHUTTLE MAIN ENGINE AND DIAGNOSTIC EVALUATION OF ADVANCED PROPULSION SYSTEM COMPONENTS Technical Progress Report
Nov. 1993 15 p
(Contract NAS8-39725)
(NASA-CR-194720; NAS 1.26:194720; TP042-121493-MS) Avail: CASI HC A03/MF A01

The Marshall Space Flight Center is responsible for the development and management of advanced launch vehicle propulsion systems, including the Space Shuttle Main Engine (SSME), which is presently operational, and the Space Transportation Main Engine (STME) under development. The SSME's provide high performance within stringent constraints on size, weight, and reliability. Based on operational experience, continuous design improvement is in progress to enhance system durability and reliability. Specialized data analysis and interpretation is required in support of SSME and advanced propulsion system diagnostic evaluations. Comprehensive evaluation of the dynamic measurements obtained from test and flight operations is necessary to provide timely assessment of the vibrational characteristics indicating the operational status of turbomachinery and other critical engine components. Efficient performance of this effort is critical due to the significant impact of dynamic evaluation results on ground test and launch schedules, and requires direct familiarity with SSME and derivative systems, test data acquisition, and diagnostic software. Detailed analysis and evaluation of dynamic measurements obtained during SSME and advanced system ground test and flight operations was performed including analytical/statistical assessment of component dynamic behavior, and the development and implementation of analytical/statistical models to efficiently define nominal component dynamic characteristics, detect anomalous behavior, and assess machinery operational condition. In addition, the SSME and J-2 data will be applied to develop vibroacoustic environments for advanced propulsion system components, as required. This study will provide timely assessment of engine component operational status, identify probable causes of malfunction, and indicate feasible engineering solutions. This contract will be performed through accomplishment of negotiated task orders. Author (revised)

A SIMULATION MODEL FOR PROBABILISTIC ANALYSIS OF SPACE SHUTTLE ABORT MODES
R. T. Hage Nov. 1993 104 p
(NASA-TM-108432; NAS 1.15:108432) Avail: CASI HC A06/MF A02

A simulation model which was developed to provide a probabilistic analysis tool to study the various space transportation system abort mode situations is presented. The simulation model is based on Monte Carlo simulation of an event-tree diagram which accounts for events during the space transportation system's ascent and its abort modes. The simulation model considers just the propulsion elements of the shuttle system (i.e., external tank, main engines, and solid boosters). The model was developed to provide a better understanding of the probability of occurrence and successful completion of abort modes during the vehicle's ascent. The results of the simulation runs discussed are for demonstration purposes only, they are not official NASA probability estimates. Author (revised)

DEBRIS/ICE/TPS ASSESSMENT AND INTEGRATED PHOTOGRAPHIC ANALYSIS FOR SHUTTLE MISSION STS-51 Report, 16 Jul. - 23 Sep. 1993
Gregory N. Katnik, Barry C. Bowen, and J. Bradley Davis Oct. 1993 153 p
(NASA-TM-109189; NAS 1.15:109189) Avail: CASI HC A08/MF A02

A debris/ice/thermal protection system (TPS) assessment and integrated photographic analysis was conducted for shuttle mission STS-51. Debris inspections of the flight elements and launch pad were performed before and after launch. Icing conditions on the external tank were assessed by the use of computer programs, nomographs, and infrared scanner data during cryogenic loading of the vehicle followed by on-pad visual inspection. High speed photography was analyzed after launch to identify ice/debris sources and evaluate potential vehicle damage and/or in-flight anomalies. This report documents the debris/ice/TPS conditions and integrated photographic analysis of Shuttle mission STS-51 and the resulting effect on the Space Shuttle Program. Author (revised)

ON-BOARD CLOSED-LOOP CONGESTION CONTROL FOR SATELLITE BASED PACKET SWITCHING NETWORKS
Pong P. Chu (Cleveland State Univ., OH.), William D. Ivancic, and Heechul Kim Dec. 1993 30 p Proposed for presentation at the 15th International Communications Satellite Systems Conference, San Diego, CA, 28 Feb. - 3 Mar. 1994; sponsored by AIAA
(Grant NAG3-1379; RTOP 235-01-04)
(NASA-TM-106446; E-8292; NAS 1.15:106446; AIAA Paper 94-1062)
Avail: CASI HC A03/MF A01

NASA LeRC is currently investigating a satellite architecture that incorporates on-board packet switching capability. Because of the statistical nature of packet switching, arrival traffic may fluctuate and thus it is necessary to integrate congestion control mechanism as part of the on-board processing unit. This study focuses on the closed-loop reactive control. We investigate the impact of the long propagation delay on the performance and propose a scheme to overcome the problem. The scheme uses a global feedback signal to regulate the packet arrival rate of ground stations. In this scheme, the satellite continuously broadcasts the status of its output buffer and the ground stations respond by selectively discarding packets or by tagging the excessive packets as low-priority. The two schemes are evaluated by theoretical queuing analysis and simulation. The former is used to analyze the simplified model and to determine the basic trends and bounds, and the later is used to assess the performance of a more realistic system and to evaluate the effectiveness of more sophisticated control schemes. The results show that the long propagation delay makes the closed-loop congestion control less responsive. The broadcasted information can only be used to extract statistical information. The discarding scheme needs carefully-chosen status information and reduction function, and normally requires a significant amount of ground discarding to reduce the on-board packet loss probability. The tagging scheme is more effective since it tolerates more uncertainties and allows a larger margin of error in status information. it can protect the high-priority packets from excessive loss and fully utilize the downlink bandwidth at the same time.

REENTRY VEHICLE ADAPTIVE TELEMETRY
R. E. Kidner Sep. 1993 66 p
(Contract DE-AC04-76DP-00789)
(DE94-001168; SAND-93-1985) Avail: CASI HC A04/MF A01

In RF telemetry (TM) the allowable RF bandwidth limits the amount of data in the telemetered data set. Typically the data set is less than ideal to accommodate all aspects of a test. In the case of diagnostic data, the compromise often leaves insufficient diagnostic data when problems occur. As a solution, intelligence was designed into a TM allowing it to adapt to changing data requirements. To minimize the computational requirements for an intelligent TM, a fuzzy logic inference engine was developed. This reference engine was simulated on a PC and then loaded into a TM hardware package for final testing. DOE

A PACKET BASED, DATA DRIVEN TELEMETRY SYSTEM FOR AUTONOMOUS EXPERIMENTAL SUB-ORBITAL SPACECRAFT
J. R. Kalibjian 26 Apr. 1993 10 p Presented at the 29th Annual International Telemetering Conference, Las Vegas, NM, 25-28 Oct. 1993
(Contract W-7405-eng-48)
(DE94-000399; UCRL-JC-112636; CONF-9310131-6) Avail: CASI HC A02/MF A01

A data driven telemetry system is described that responds to the rapid nature in which experimental satellite telemetry content is changed during the development process. It also meets the needs of a diverse experiment which the many phases of a mission may contain radically different types of telemetry data. The system emphasizes mechanisms for achieving high redundancy of critical data. A practical example of such an implementation, Brilliant Pebbles Flight Experiment Three (FE-3), is cited. DOE

AUTOMATED ANALYSIS TOOLS FOR REDUCING SPACECRAFT TELEMETRY DATA
T. J. Voss 26 Apr. 1993 9 p Presented at the 29th Annual International Telemetering Conference, Las Vegas, NV, 25-28 Oct. 1993
(Contract W-7405-eng-48)
(DE94-000400; UCRL-JC-112639; CONF-9310131-3) Avail: CASI HC A02/MF A01

A practical description is presented of the methods used to reduce spacecraft telemetry data using a hierarchical toolkit of software programs developed for a UNIX environment. A project requiring the design, implementation, and test flight of small, lightweight spacecraft was recently conducted. This spacecraft development required hundreds of tests and integrations of subsystems on several special purpose testbeds, with each test creating large amounts of telemetered data. Focus is on the automated analysis and reduction of data which is telemetered from one of the key subsystems, the Probe. A typical telemetry stream from a testbed run averaged 50 Megabytes of raw data, containing over 1600 system variables. The large telemetry file (raw data) sent from the Probe was decoded and decomposed into a large number of smaller Break Out Files (BOF's) containing variables with timestamps, and image files. DOE

POINTING CONTROL DESIGN FOR AUTONOMOUS SPACE VEHICLE APPLICATIONS
K. D. Young Mar. 1993 7 p Presented at the 12th International Federation of Automatic Control World Congress, Sydney, Australia, 19-23 Jul. 1993
(Contract W-7405-eng-48)
(DE93-019943; UCRL-JC-113458; CONF-930781-2) Avail: CASI HC A02/MF A01

This paper addresses the design of pointing control systems for autonomous space vehicles. The function of the pointing control system is to keep distant orbiting objects within the field-of-view of an on-board optical sensor. We outline the development of novel nonlinear control algorithms which exploit the availability of onboard sensors. Simulation results comparing the performance of the different pointing control implementations are presented. DOE

THE NRL LACE PROGRAM Final Report
D. M. Horan, R. E. Perram, and R. E. Palma 27 Aug. 1993 37 p
(AD-A270861; NRL/FR/8121-93-9565) Avail: CASI HC A03/MF A01

The Naval Research Laboratory's Low-power Atmospheric Compensation Experiment (LACE) Program was established to provide and operate a satellite that could carry and support instruments to measure the intensity and distribution of low-energy laser beams transmitted from Earth; to image the ultraviolet emission from rocket plumes at high altitudes; and to measure the spectrum and distribution of terrestrial neutrons. The satellite was launched on 14 February 1990. It made many successful laser beam measurements; collected high-quality emission images from four rocket launches in four attempts; and made neutron background measurements almost continuously for 36 months. DYNAMICS EXPLORER 2: CONTINUED FPI AND NACS INSTRUMENT DATA ANALYSIS AND ASSOCIATED SCIENTIFIC ACTIVITY AT THE UNIVERSITY OF MICHIGAN Final Report, Dec. 1990 - 31 Jan. 1994
Alan Burns and T. L. Killeen 7 Dec. 1993 16 p
(Grant NAG5-465)
(NASA-CR-194689; NAS 1.26:194689) Avail: CASI HC A03/MF A01

The grant entitled 'Dynamics Explorer 2 - continued FPI and NACS instrument data analysis and associated scientific activity at the University of Michigan' is a continuation of a grant that began with instrument development for the Dynamics Explorer 2 (DE 2) satellite. Over the years, many publications and presentations at scientific meetings have occurred under the aegis of this grant. This present report details the progress that has been made in the final three years of the grant. In these last 4 years of the grant 26 papers have been published or are in press and about 10 more are in preparation or have been submitted. A large number of presentations have been made in the same time span: 36 are listed in Appendix 2. Evidence of the high educational utility of this research is indicated by the list of Ph. D. and M. S. theses that have been completed in the last 3 years that have involved work connected with NAG5-465. The structure of this report is as follows: a brief synopsis of the aims of the grant NAG5-465 is given in the next section; then there is a summary of the scientific accomplishments that have occurred over the grant period; last, we make some brief concluding remarks. Reprints of articles that have recently appeared in refereed journals are appended to the end of this document. Derived from text

THE EXOSAT OPERATIONAL EXPERIENCE
A. G. Parkes, P. T. Prior, and D. Heger Jun. 1993 93 p
(ESA-STM-248; ISBN-92-9092-357-1; ETN-93-94879) Copyright Avail: CASI HC A05/MF A01

The European X-ray Observatory Satellite (EXOSAT) system is reviewed. Those areas which gave rise to operational problems are highlighted. EXOSAT was launched on 26 May 1983 after definition, design, and development phases for both the space and ground systems and a number of launch delays. The planned mission lifetime was two years. This target was duly achieved, and the experiments continued to return scientific data until 9 Apr. 1986. Approximately one month later, on 6 May 1986, the orbit decayed and the spacecraft reentered the Earth's atmosphere. The wealth of scientific data received and the important and exciting scientific discoveries emerging from EXOSAT led to the mission being justifiably described within the scientific community as a 'great success.' SPACE STATION TRASH REMOVAL SYSTEM Patent
Andrew J. Petro, inventor (to NASA) 7 Sep. 1993 5 p Filed 22 May 1992 Supersedes N92-30315 (30 - 21, p 3588)
(NASA-Case-MSC-21723-1; US-Patent-5,242,134;

US-Patent-Appl-SN-887001; US-Patent-Class-244-158R; US-Patent-Class-244-160; Int-Patent-Class-B64G-1/22) Avail: US Patent and Trademark Office

A trash removal system for space stations is described. The system is comprised of a disposable trash bag member and an attached, compacted large, lightweight inflatable balloon element. When the trash bag member is filled, the astronaut places the bag member into space through an airlock. Once in the vacuum of space, the balloon element inflates. Due to the large cross-sectional area of the balloon element relative to its mass, the combined balloon element and the trash bag member are slowed by atmospheric drag to a much greater extent than the Space Station's. The balloon element and bag member lose altitude and re-enter the atmosphere, and the elements and contents are destroyed by aerodynamic heating. The novelty of this system is in the unique method of using the vacuum of space and aerodynamic heating to dispose of waste material with a minimum of increase in orbital debris.

TETRAHEDRAL LANDER Patent

Michael L. Roberts, inventor (to NASA) 30 Nov. 1993 7 p Filed 3 Feb. 1993 Supersedes N94-15951 (32 - 3, p 886)
(NASA-Case-MSC-22082-1; US-Patent-5,265,829; US-Patent-Appl-SN-012839; US-Patent-Class-244-160; US-Patent-Class-244-138A; US-Patent-Class-244-100A; US-Patent-Class-244-110D; US-Patent-Class-244-113; US-Patent-Class-244-158A; US-Patent-Class-244-138R) Avail: US Patent and Trademark Office

An apparatus and method is disclosed for decelerating and absorbing impact of a re-entry vehicle suitable for payloads that are relatively light as well as payloads weighing several tons or more. The apparatus includes four inflatable legs displaced equidistantly from each other around a capsule or housing which contains a payload. The legs are inflated at a designated altitude after entering earth's atmosphere to slow the descent of the re-entry vehicle. Connected between each of the four legs are drag inducing surfaces that deploy as the legs inflate. The drag inducing surfaces are triangularly shaped with one such surface being connected between each pair of legs for a total of six drag inducing surfaces. The legs have drag inducing outer surfaces which act to slow the descent of the re-entry vehicle.

UVPI IMAGING FROM THE LACE SATELLITE: THE STARBIRD ROCKET PLUME

H. W. Smathers, D. M. Horan, J. G. Cardon, E. R. Malaret, and L. Perez 18 Aug. 1993 141 p
(AD-A271981; NRL/FR/8105-93-9546) Avail: CASI HC A07/MF A02

The Starbird rocket provides the second demonstration of the ability of the Ultraviolet Plume Instrument (UVPI) to observe missiles in flight above the atmosphere. The Starbird was launched from the Kennedy Space Center in Florida on 18 December 1990. The UVPI is a small, plume-tracking instrument flown on the Naval Research Laboratory's Low-power Atmospheric Compensation Experiment (LACE) satellite, launched in February 1990. The two cameras of the instrument, a tracker and a plume camera, use filters, image intensifiers, and CCD detectors to observe sources in the ultraviolet. The plume camera has a narrow field of view, 0.180 deg by 0.135 deg, and observes sources through any of the four filters with passbands of 195 to 295 nm, 200 to 300 nm, 235 to 350 nm, and 300 to 320 nm. The Starbird third and fourth stages, both of which used identical Orbus rocket motors, reached 90-km altitude and were successfully detected and tracked by the UVPI from a range of 596 to 483 km. The spectral radiance and intensities of the missile plumes were extracted from these images and made into contour plots. Spatial, temporal, and spectral characteristics of the plume are also provided. DTIC

METHOD OF ORIENTING A SYNCHRONOUS SATELLITE Patent

Lawrence H. Westerlund, inventor (to Communications Satellite Corp.) 28 Jul. 1992 63 p Filed 23 Aug. 1988
(CA-Patent-1,305,772; Int-Patent-Class-B64G-1/10; CTN-93-60690)

Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

A method is provided which has the objective of solving the problems involved in orienting a satellite in geosynchronous orbit. In a first embodiment, the method includes a step of orienting the spin axis of the satellite at orbit-normal. The direction angle is measured in a rotational direction from a first line which represents equatorial normal to a second line which represents orbit-normal, where the first and second lines intersect at the satellite's center of mass. In a second embodiment, the method includes a step of orienting the spin axis at orbit-normal plus a correction angle determined according to equations whose parameters include the elevation angle and latitude of the bore site target, and the inclination angle of the orbital plane with respect to the equatorial plane. In this embodiment, the direction angle is measured as in the first embodiment. The step of orienting the spin axis can be performed by firing thrusters. The method of the invention can be easily performed, and the advantage of vastly prolonging the useful life of a satellite by reducing or discontinuing north/south stationkeeping can be easily achieved, even with satellites already in orbit.

LONG DURATION EXPOSURE FACILITY (LDEF) CONTAMINATION STUDY Final Report

Karen P. Scott Oct. 1993 16 p
(Contract N00014-90-J-4052)
(AD-A272419) Avail: CASI HC A03/MF A01

This report describes the optical measurements that were taken of LDEF surfaces during the deintegration of LDEF from February to April 1990. This project was one part of an overall effort conducted by Boeing Aerospace to determine and track contamination on LDEF. The purpose of this portion of the contamination project was to provide early documentation of the contamination level on LDEF experiments before shipment and disassembly by the principle investigators (PI). 35% of experiment trays located on all areas of LDEF were examined to, in particular, catalogue global differences in contamination depending on tray location. The optical measurements were performed with a Model BHMJ Nomarski microscope which had also darkfield and oblique lighting capabilities. The optical measurements were documented by video and 35-mm cameras that could be attached to the microscope. Approximately 15 hours of video and 17 rolls of film (24 exposure) were taken. A full list of all trays and experiments observed is presented in Appendix C. Due to the high volume of data, a short 10-min. video has been compiled to illustrate the different contamination processes observed on LDEF. DTIC

A CONCEPTUAL DATABASE DESIGN AND PERFORMANCE ANALYSIS OF THE MILSATCOM REQUIREMENTS DATABASE M.S. Thesis

Ronald G. Kearns Jun. 1993 87 p
(AD-A272672) Avail: CASI HC A05/MF A01

The Military Satellite Communications Decision Support System (MDSS) project for U.S. Space Command (USSPACECOM) is intended to provide decision makers an integrated information tool to effectively manage military satellite communication (MILSATCOM) resources while satisfying communications requirements. An important aspect of MDSS is the information provided by the MILSATCOM Requirements Database (MRDB). The objective of this thesis is twofold. First, it develops a new conceptual schema for the MRDB using the Entity Relationship Model and transforms it into a relational schema for implementation. Second, it conducts a comparative performance analysis to examine the tradeoffs between normalization and performance. This thesis concludes that a structured approach to designing the MRDB results in a normalized structure that is simple, easy to implement, and provides acceptable performance. A fully normalized database structure does not seem to have a significant impact on over-all MRDB retrieval performance. DTIC

DESIGN AND IMPLEMENTATION OF A PROTOTYPE PC BASED GRAPHICAL AND INTERACTIVE MILSATCOM REQUIREMENTS DATABASE SYSTEM M.S. Thesis

William M. Major Jun. 1993 137 p

(Contract MIPR-NS-93-76)
(AD-A272960) Avail: CASI HC A07/MF A02

This thesis develops a prototype PC based Military Satellite Communications (MILSATCOM) Requirements Database (MRDB) application for U.S. Space Command, using Microsoft's Access relational database management system (DBMS) for Windows. It demonstrates the advantages of using the proposed database system over the existing one and shows how U.S. Space Command can save both time and money by using a PC based interactive, graphical, and user friendly database system. A rapid prototyping approach in concert with a six phase database design process was used to develop the prototype. The first two chapters of the thesis provide a background of the application and describe database management systems in general and Microsoft Access in particular. The applications of Access - tables, queries, forms, reports, macros, and modules - to the design of the MRDB are then discussed in the succeeding five chapters. The conclusions describe the advantages and benefits of using the prototype MRDB database system and make recommendations for future improvements. DTIC

Results obtained from the Long Duration Exposure Facility (LDEF) and Mir Aragatz experiments are reviewed. Research in connection with atomic oxygen (effects, modeling, simulation, means of protection, etc.) is reported. The following are discussed: environment models (communication of the most recent use of the one best suited to the problem in hand); contamination and its effects (old problem/new data); ground testing (standardization/measurement standards); and functional deterioration of lubrication materials used in low orbit. For individual titles, see N94-21368 through N94-21408.

Experiments devoted to the detection of cosmic dust in space are reported. One was located on the Long Duration Exposure Facility (LDEF) and one on the Soviet Mir Space Station. A variety of sensors and collecting devices made possible the study of the particles and their effects after recovery of exposed material. Flux mass distribution is expected to be derived with a good accuracy due to the large time area exposure. Understanding of the mechanism of impact process on materials currently used in space will be greatly improved after full analysis of data impacts on metals, fiberglass thermal covers, and quartz samples are reported. Remnants of particles suitable for chemical identification are found within impact craters. A discrimination between extraterrestrial particles and man-made orbital debris is expected. Preliminary examination of hypervelocity impact features gives valuable information on size distribution and nature of interplanetary dust particles in low earth orbit, within the 0.5 to 300 micrometer size range. So far, chemical investigation of craters found on LDEF clearly shows evidence of elements (Na, Mg, Si, S, Ca, and Fe) consistent with cosmic origin. It is suggested that thin foil detectors for chemical investigation of particle remnants within impact sites would be promising for future experiments. ESA

Two experiments which evaluated the deterioration of materials in orbit and validated laboratory simulation techniques are reported. One was flown on the trailing edge of the Long Duration Exposure Facility (LDEF) and the other outside the Mir Space Station. Approximately 200 specimens of about 60 different materials were exposed in LEO (low earth orbit) conditions: their pre- and post-exposure properties were measured under laboratory conditions in air. The tested materials included thermal control coatings, polymers, protective layers against atomic oxygen, composite materials, and optical components. Most specimens were passively subjected to the space environment. Several sets of four identical specimens enabled investigation of the effects of the combined action of oxygen atoms and UV radiation and a comparison of these with the effects of solar UV radiation acting alone. Some samples were placed inside a canister which was opened and closed in orbit whereas others were submitted to the complete environment of the LDEF mission in order to evaluate possible contamination effects. The results provided valuable information on the performance of materials and the damage mechanisms experienced in orbit. Some typical material behavior examples are given. Particular emphasis is placed on the synergistic effects of the natural and induced components of the space environment. Some results of laboratory tests and in-flight tests can be compared. As a consequence the limitation of both flight and laboratory environment tests is examined. ESA

Data gathered by the Interim Operational Contamination Monitor (IOCM) with regard to the effect of the space environment on the STS-32 Shuttle mission and on the Long Duration Exposure Facility (LDEF) are reported. IOCM measures the deposition of molecular and particulate contamination during all flight phases. It also measures the thermophysical properties of thermal control surfaces by calorimetry, the flux of the ambient atomic oxygen environment, the incident solar flux, and the absolute ambient pressure in the payload bay. The IOCM also provides a structure and sample holders for the exposure of passive material samples to the space environment. One of the more salient results from the STS-32 flight suggests that the LDEF emitted a large number of particulates after berthing into the Shuttle. The mission atomic oxygen fluence was also calculated. Although the fluence was low by normal standards, the Kapton (trademark) passive samples exhibited the onset of erosion. Orbital debris and micrometeoroid impacts also occurred during the retrieval mission. The average perforation diameter was approximately 1.25 micrometers. The largest perforation diameter was measured at 65 micrometers. ESA

SOME RESULTS OF THE OXIDATION INVESTIGATION OF COPPER AND SILVER SAMPLES FLOWN ON LDEF **c26**

A. deRooij *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 119-129 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Copper strips flown on the Long Duration Exposure Facility (LDEF) were partially exposed to the atomic oxygen environment present at the LDEF altitude. Depending on the sample position the copper strips show a surface darkening due to the presence of an oxide layer. The type of oxide is investigated as well as its thickness. The silver samples were part of an Ultra Heavy Cosmic Ray Experiment (UHCRE) thermal blanket. This thermal blanket consists of Teflon A-FEP (127 micrometers) + Silver (1600 A) + Inconel (400 A) + Black Paint Chemglaze Z306 (50 to 70 micrometers). The Teflon A-FEP was exposed to the space environment. After penetration of the Teflon A-FEP by a micrometeoroid, the underlying silver was oxidized, where the oxide manifested itself as circular rings around the micrometeoroid hole. An alternating pattern of oxygen and fluor was measured across these rings. ESA

Observations and measurements carried out during the MAPOL (French acronym for polymer materials) experiment which took place on the Space Station Mir during the french-Soviet Aragatz flight are reported. The aim was to evaluate the effect of the space environment on the mechanical and thermooptical properties of materials which could be used for different applications such as non-rigid space stations, and large dimension inflatable and rigidifiable masts. Different aramid materials were tested. These were exposed without protection, and with protective layers of polymers and fluorine-containing substances of different thicknesses. ESA

THE IMPLICATIONS OF THE LDEF RESULTS ON SPACE STATION FREEDOM POWER SYSTEM MATERIALS

Bruce A. Banks, Sharon K. Rutledge, Kim K. deGroh, Michael J. Mirtich, Linda Gebauer (Cleveland State Univ., OH.), Raymond Olle (Cleveland State Univ., OH.), and Carol M. Hill (Ohio Aerospace Inst., Brook Park.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 137-154 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Results and implications of Long Duration Exposure Facility (LDEF) exposure of materials relevant to the Space Station Freedom (SSF) power system materials are presented. Atomic oxygen interactions with potential synergistic UV effects on silicone materials on LDEF were shown to result in the deposition of a dark contaminant film on adjoining surfaces. Silicones associated with solar array construction have the potential for causing reduced solar illumination of the solar cells if such silicone molecular fragments are found to be surface mobile. Results of LDEF atomic oxygen protective coatings on polyimide Kapton indicated acceptable durability to the synergistic effects of atomic oxygen, UV, thermal cycling, and micrometecroid or debris impact. Results of combined atomic oxygen, UV radiation, thermal cycling, and micrometeoroid and debris impacts on LDEF high emittance radiator coatings indicate long term emittance and absorptance durability of Z 93 (zinc oxide pigment in a potassium silicate binder) coatings which have been selected for SSF radiator surfaces. CALIBRATION OF A CALORIMETER FOR MEASURING THE PERFORMANCE OF THERMAL CONTROL SURFACES **c35**

John Houseman and Georg Siebes *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 155-168 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

The calibration to evaluate the heat leak in terms of the deviation from

a perfect calorimeter is described. A thermal vacuum test was carried out to characterize the performance of the calorimeter. The calorimeter was equipped with a heater to control the sample disc temperature and with specific instrumentation to measure the heat leak. The radiation sink temperature of the black cavity target was varied from -192 to +31C, while the heater power was varied from 0 to 311 milliwatts. A steady state thermal model was developed to correlate the results. The calorimeter performance was characterized in terms of the heat leak as a percentage of the ideal heat flow of the calorimeter disc. Large deviations from ideal performance occur at low sink temperatures. The effect of the use of the heater is discussed. The effects of transient conditions during low Earth orbit are discussed. It is concluded that heat leak calibrations are necessary for a wide range of conditions. ESA

THERMAL STRESS ANALYSIS OF COMPOSITES IN THE SPACE ENVIRONMENT **c24**

David E. Bowles *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 171-186 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A finite element micromechanics approach was utilized to investigate the thermally induced stress fields in continuous fiber reinforced polymer matrix composites at temperatures typical of spacecraft operating environments. The influence of laminate orientation was investigated with a simple global/local formulation. Thermal stress calculations were used to predict probable damage initiation locations, and the results were compared to experimentally observed damage in several epoxy matrix composites. The influence of an interphase region on the interfacial stress states was investigated. ESA

THE SIMULATION OF ACTION OF SOME SPACE ENVIRONMENT FACTORS ON TEFLON AND ON RUBBER MATERIALS **c27**

V. E. Skurat, E. A. Barbashev, Y. I. Dorofeev, B. I. Khrushch, A. V. Milinchuk, and V. V. Sedov *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 187-196 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

The mechanical properties of Fluoroplast 4 Teflon (trademark) films with thickness 20 micrometers were measured after the irradiations: by sunlight in Low Earth Orbit (LEO); in the test chamber 'Sun' by light with wavelength longer than 220 nm; by light 147 nm from resonance Xe lamp; and by light from deuterium lamp with wavelength longer than 177 nm. The main contribution to the deterioration of mechanical properties of this polymer when irradiated by sunlight in LEO gives the VUV radiation with wavelength from 170 to about 200 to 220 nm. Light with longer and shorter wavelengths does not reproduce the efects of Sun irradiation. A method for screening the resistance of rubber materials to action of VUV, UV light and oxygen plasma is developed. The method is based on microscopic observations of surface of materials after their irradiation in stretched state. The deterioration of hermetic ability of rubber material is observable after a few minutes of exposition. This time is 30 to 50 times shorter than in usual techniques. ESA

N94-21381 National Research Council of Canada, Vancouver (British Columbia).

IN-VACUO SLIP TESTING OF MATERIALS FOR SSRMS FRICTION BRAKES **c27**

H. M. Hawthorne and S. Preston (Spar Aerospace Ltd., Weston, Ontario.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 197-208 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

An investigation involving the screening of potential materials to be used as friction pads on the Space Station Remote Manipulator System (SSRMS) brakes and clutch assemblies, and the intensive, long term (15 weeks) testing, under high vacuum, of the selected candidate materials, is reported. Screening tests identified ceramic/cermet materials which, after appropriate interface engineering to develop stable wear debris morphology, provide high friction in a vacuum environment, indefinitely. The first material selected, a refractory ceramic, successfully underwent slip testing during extended (15 weeks) exposure to high vacuum and at temperatures of -40 to 96 C, as well as ambient. Frictional stability and good wear resistance was demonstrated by this ceramic material, which makes it a viable choice for use as a friction element on the SSRMS brakes and clutch assemblies. ESA

EFFECT OF GEOSTATIONARY ENVIRONMENT CONSTITUENTS ON SECONDARY ELECTRON EMISSION RATES

R. Reulet, J.-M. Siguier, L. Levy, and F. Levadou (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 209-219 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Variations of Secondary Electron Emission (SEE) yield of a PST OSR type material covered with an ITO thin film, induced by geosynchronous orbit representative parameters, are shown. The following results were obtained: the simulated electrons and protons doses, corresponding to 6, 12 and 24 months duration in geosynchronous orbit, slightly modify the SEE yield of irradiated samples; in the same way, UV irradiation of 36 months has a slight influence on the SEE yield; protons + electrons and UV irradiations seem to modify SEE properties by their ability to fix on bombarded surfaces, residual gases, or particles of the chamber; the SEE yield is clearly decreased by increasing the RTV 566 contaminant thickness; an electron + proton or UV irradiation on a contamined surface has no detectable effect on the SEE yield. It is concluded that pollution seems to be the prominent factor on the SEE yield modification of treated surfaces, and Electron Spectroscopy for Chemical Analysis (ESCA) analysis confirm this hypothesis. ESA

ELECTROSTATIC CHARGING AND SECONDARY EFFECTS IN MATERIALS SUBMITTED TO RADIATION IN SPACE [DECHARGES ET EFFETS SECONDAIRES DANS LEX MATERIAUX SOUMIS AUX RAYONNEMENTS DANS L'ESPACE]

Y. Tutrin, A. Akichin, D. Ledyankin, and L. Novikov *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 221-228 In FRENCH (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A study to examine the nature and factors responsible for the accumulation of electrostatic charges on exposed materials in space is reported. The laboratory simulation of this charge accumulation on insulating materials exposed to radiation and bombarded by artificial micrometeoroids is reported. Secondary effects such as the emission of charged particles are brought about. A method of inciting the electrostatic charges using laser beams in optical glass exposed to radiation is described. The experimental data of the temporal properties of the provoked discharges are considered. ESA

High performance polymers for potential space applications were evaluated under simulated space environmental conditions. Experimental resins from blends of acetylene terminated materials, poly(arylene ether)s and low color polyimides were exposed to high energy electron and ultraviolet radiation in an attempt to simulate space environmental effects. Thin films, neat resin moldings, and carbon fiber reinforced composites were exposed, and the effect on certain polymer properties were determined. Recent research involving the effects of various radiation exposures on the physical, optical, and mechanical properties of several experimental polymer systems is reviewed. ESA

MATERIALS EVALUATION AT ESA/ESTEC **c23**

G. Gourmelon, M. Froggatt, and D. Collins *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 255-272 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A method of evaluating materials that are intended to be used in space is presented. The materials evaluated include thermal control coatings and films, conformal coatings, adhesives, adhesive tapes, primers and surface protection treatments, metals and solderless/mechanical electrical connection techniques. However, other materials or combination of materials can also be assessed by this method. The described evaluation program is divided into parts in order to provide a methodical and efficient procedure of test. The material evaluation should only pass to the following part if the material has satisfied the conditions of the previous part. This avoids waste of effort and expense on the more costly tests. Results of the following types of tests on ITO (indium tin oxide)/Kapton/VDA (vacuum deposited aluminum) and on McGHAN-NUSIL CV-1152 are given: outgassing, surface resistivity, chemical, humidity, thermal cycling, thermal shock, bend, adhesion, flammability, and offgassing. ESA

COLUMBUS: MATERIALS FOR 30 YEARS HABITABILITY IN SPACE

D. Zanotti *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 273-290 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A general assessment of the problem of the selection of materials to be used inside the Columbus habitable modules is provided. Basic safety requirements and system engineering considerations are described. Special emphasis was put on ground testing and materials screening, acceptance and ranking problems. Newly developed tests or original adaptation of existing ones are described. Some important relationships between the criteria for approval of materials, residual safety hazards, and design solutions are mentioned. The importance and complexity of the problems of the habitable environment in manned spacecraft that need to be addressed (toxicology, human factors engineering, microbiology, etc.) are emphasized. The need for a more systematic approach to materials selection which implies that the materials discipline shall become much more integrated into the design process, during all its phases, is stressed. METEOROIDS AND DEBRIS IMPACT RISK ASSESSMENT ON COLUMBUS AND HERMES USING A REALISTIC GEOMETRICAL ANALYSIS TOOL

J. Borde and G. Drolshagen (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 291-310 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

An enhanced three-dimensional (3D) numerical analysis tool for meteoroid/space debris risk evaluation was developed. It provides impact probabilities and resulting damage effects using realistic geometrical treatments and is based on presently available environment and particle/wall interaction models together with spacecraft shielding design. This tool is used for evaluating the risk of impacts on the Columbus Attached Pressurized Module (APM) and the Hermes Spaceplane. The more recent spacecraft geometry (ESABASE model), orbital parameters, pointing directions, environment models, and shielding configuration are employed. On each elementary surface of the spacecraft, the number of impacts, the number of failures, the mean velocity amplitude, the mean velocity elevation angle, and the percentage of cratered area are computed. This allows the critical parts of the spacecraft to be determined, i.e., the surfaces which require more shielding. For both spacecraft, some significant results and recommendations are provided. ESA

N94-21389 MATRA Marconi Space, Toulouse (France).

COMBINATION OF ON GROUND EXPERIMENTS AND ANALYSIS SOFTWARE FOR THE EVALUATION OF MATERIAL DEGRADATION IN SPACE (SILEX PROJECT) **c61**

P. Renard *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 311-320 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

An assessment study which combines analysis software for the prediction of atomic oxygen fluence and micrometeoroid impacts with laboratory tests to characterize the degradation they induce in the optical equipment of the optical intersatellite communications experiment SILEX, is presented. The software uses environment models and the ray tracing Monte Carlo technique. The laboratory tests assessed micrometeoroid impact both at the surface level and at the optical properties level, and some of the worst cases of damage were derived. ESA

N94-21390 Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Cologne (Germany).

GERMAN SPACE EXPERIMENTS ON SPACELAB D-2 AND EURECA-1 TO INVESTIGATE ATOMIC OXYGEN INTERACTION WITH MATERIALS **c25**

H. Hamacher and H. E. Richter *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 323-330 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Two complementary passive space experiments to investigate atomic oxygen interactions with spacecraft materials, primarily those intended to be used for the Atomic Oxygen Sample Tray (AOST) to be flown on Eureca (European retrievable carrier) and the Atomic Oxygen Exposure Tray which is part of the German Spacelab D-2, are presented. The total atomic oxygen fluences of both missions are on the order of 10(exp 20) atoms/sq cm. The identical materials will be examined in both experiments to determine the material recession rate degradation for different exposure times and ambient atmospheres. The materials selected are mainly candidates for Columbus and other elements of the upcoming orbital infrastructure: fibers and matrix materials for composites; coatings, paints, and materials for thermal blankets; and electrical contacts. THE INTERNATIONAL TELECOMMUNICATIONS SATELLITE (INTELSAT) SOLAR ARRAY COUPON (ISAC) ATOMIC OXGYEN FLIGHT EXPERIMENT: TECHNIQUES, RESULTS AND SUMMARY **c44**

S. Koontz, G. King, A. Dunnet (International Telecommunications Satellite Organization, Washington, DC.), T. Kirkendahl (Communications Satellite Corp., Washington, DC.), R. Linton (National Aeronautics and Space Administration. Marshall Space Flight Center, Huntsville, AL.), and J. Vaughn (National Aeronautics and Space Administration. Marshall Space Flight Center, Huntsville, AL.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 331-348 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Techniques and results of the ISAC flight experiment are presented, and comparisons between flight tests results and ground based testing are made. The ISAC flight experiment, one component of a larger INTELSAT 6 rescue program, tested solar array configurations and individual silver connects in ground based facilities and during STS-41 (Space Shuttle Discovery). In addition to the INTELSAT specimens, several materials, for which little or no flight data exist, were also tested for atomic oxygen reactivity. Dry lubricants, elastomers, polymeric materials, and inorganic materials were exposed to an oxygen atom fluence of 1.2 x 10(exp 20) atoms. Many of the samples were selected to support Space Station Freedom design and decision-making. ESA

DURABILITY OF THERMAL CONTROL AND ENVIRONMENTAL PROTECTIVE MATERIALS FOR THE SSRMS IN SIMULATED LEO ENVIRONMENT

S. K. Chang *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 349-367 Sponsored by Canadian Space Station Program (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Nine thermal control and environmental protection materials, selected on the basis of their space pedigree, thermal vacuum stability, and thermo-optical properties, were tested to determine their suitability for the Space Station Remote Manipulator System (SSRMS). The ground based testing was carried out to simulate the effects of atomic oxygen and thermal cycling in the Low Earth Orbit (LEO) environment. These factors are deemed most likely to cause degradation to the selected materials. With the exception of the urethane based coatings, the materials tested demonstrate sufficient resistance to atomic oxygen. The detrimental effect of thermal cycling on the adhesion of the silicate based coatings to aluminum substrate was found to depend on the pigment. A separate experiment on Beta-Cloth showed that its thermo-optical properties remained substantially unchanged as the Teflon coating was progressively removed in a plasma asher. ESA

ATOMIC OXYGEN INTERACTION WITH SPACECRAFT MATERIALS: RELATIONSHIP BETWEEN ORBITAL AND GROUND-BASED TESTING FOR MATERIALS CERTIFICATION **c25**

Jon B. Cross (Los Alamos National Lab., NM.), Steven L. Koontz, and Esther H. Lan (McDonnell-Douglas Space Systems Co., Huntington Beach, CA.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 369-384 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

The effects of atomic oxygen on boron nitride (BN), silicon nitride (Si3N4), Intelsat 6 solar cell interconnects, organic polymers, and MoS2 and WS2 dry lubricant, were studied in Low Earth Orbit (LEO) flight experiments and in a ground based simulation facility. Both the inflight and ground based experiments employed in situ electrical resistance measurements to detect penetration of atomic oxygen through materials and Electron Spectroscopy for Chemical Analysis (ESCA) analysis to measure chemical composition changes. Results are given. The ground based results on the materials studied to date show good qualitative correlation with the LEO flight results, thus validating the simulation fidelity of the ground based facility in terms of reproducing LEO flight results. In addition it was demonstrated that ground based simulation is capable of performing more detailed experiments than orbital exposures can presently perform. This allows the development of a fundamental understanding of the mechanisms involved in the LEO environment degradation of materials. ESA

The results of evaluations of thin film protective layers applied to selected organic substrates (Kapton polyimide, graphite/epoxy, and amorphous carbon) that have been shown to be attacked by atomic oxygen are reported. These protective films, derived from volatile compounds via microwave glow discharge, include amorphous hydrogenated silicon, inorganic silicon compounds, and organosilicones. These materials were exposed to attack from atomic oxygen oxygen beam bombardment, while sensitive measurements of mass loss rate and total mass loss were made in situ using Quartz Crystal Microbalances (QCM's) coated with the candidate materials. The results of mass loss measurements show that the coatings provide excellent protection compared to unprotected specimens of the same materials. Results from high energy (20 keV) electron beam bombardment show that P-SiO2 and SiN coatings on Kapton prevent discharge occurrence while other coating substrate combinations result in discharge modification with respect to both peak current, and discharge frequency and duration. Mechanical loading and thermal stressing confirmed that the coatings adhere tightly to the substrate and remain intact up to the point of fracture of the underlying material. Thermal radiative property measurements are presented for protective films which show little change from the uncoated materials in the virgin state both before as well as after exposure to atomic oxygen attack. The results of space flight tests which corroborate the laboratory results are presented. ESA

N94-21395 Physical Sciences, Inc., Andover, MA.

FAST OXYGEN ATOM STUDIES RELATED TO LOW EARTH ORBIT ACTIVITIES Abstract Only

G. E. Caledonia, R. H. Krech, K. W. Holtzclaw, and D. Sonnenfroh *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 403 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

The technique of laser induced gas breakdown to develop a high flux pulsed source of fast oxygen atoms (v = 5 to 12 km/s) is considered. The technique is also used to produce high velocity beams of N/N2 mixtures and can be extended to produce beams of other species. The fast oxygen atoms are of particular current interest since this is the dominant atmospheric species encountered by spacecraft operating in Low Earth Orbit (LEO). The fast oxygen atom source has proven extremely versatile and is used to study a variety of gas-surface and gas-gas collision phenomena. The fast atom facility has reproducibly provided good comparison with LEO observations. Expanded programs involving material testing and measurement of O atom momentum and energy accommodation coefficients with surfaces are presently underway. ESA

ATOMIC OXYGEN FLUENCE DETECTOR FOR BREMSAT: SCIENTIFIC AND TECHNICAL DESCRIPTION **c19**

G. Drolshagen and M. VanEesbeek *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 405-408 (For primary document see N94-21367 05-18)

Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A detector which will be upgraded to proto-flight model to be flown on Bremsat and other future missions is presented. The detector basically consist of 2 carbon coated Quartz Crystal Microbalances (QCM) with the associated electronics and interfaces. A QCM measures frequency changes

due to mass change. It can be used both for mass deposition and erosion. The detector will be exposed to the direct O flux for about 5% of each Bremsat rotation period. Preliminary calculations show that this will correspond to some 1.9 times 10 to the 20th power O atoms/sq cm over the complete mission. After completion of the mission a detailed analysis will be performed comparing the measurements to the predictions obtained from the latest atmosphere models. ESA

HYPERVELOCITY IMPACT STUDIES AT CEG: EXPERIMENTAL AND NUMERICAL CAPABILITIES Abstract Only [LES MOYENS EXPERIMENTAUX ET NUMERIQUES DU CEG POUR LES ETUDES D'IMPACT HYPERVITESSE] **c39**
C. Loupias and B. Jimenez *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 409-410 In ENGLISH and FRENCH (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Experimental and numerical facilities to study hypervelocity impacts are addressed. The CEG (Centre d'Etudes de Gramat) experimental facilities mainly consist of a two stage light gas gun which can accelerate 1 to 5 grams projectiles up to 8 km/s, with full knowledge and repeatability of the impact conditions. The experimenter can choose the nature, shape and mass of the projectile, moreover he exactly knows the projectile state just before impact. For the diagnosis of hypervelocity impacts, specific instrumentation is associated with launcher: Lagrangian gauges, velocity interferometers, flash X-ray systems, infrared Crantz-Schardin camera, ultra high speed pyrometer. The numerical capabilities are also suited for numerical simulations of hypervelocity impacts: powerful computers, two dimensional and three dimensional codes (HULL, EPIC, etc.). This set of experimental and numerical capabilities can be used, on the one hand to characterize dynamic behavior of materials under hypervelocity impact and, on the other hand, to suggest and test new concepts of spacecraft bumper shields. ESA

FORECASTING TECHNIQUE OF VARIATIONS OF THE OPTICAL ABSORPTIVITY OF THERMAL CONTROL COATINGS UNDER DIFFERENT SIMULTANEOUS RADIATIONS **c27**
A. P. Grashchenko and G. G. Soloviev *In its* Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 413-426 (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Thermal control coatings with high reflectivity are considered with emphasis upon a model of the behavior of the integral optical absorptivity under different radiations. Since the change in the integral absorptivity of solar radiation is equal to the corresponding change in the reflectivity, the latter is discussed. Experimental results are presented. ESA

N94-21400 Centre National d'Etudes Spatiales, Toulouse (France).
THERMAL CONTROL COATINGS **c27**
Jean-Claude Guillaumon and Francoise Guerard (MAP S.A., Pamiers, France.) *In its* Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 427-433 (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

Thermal control coatings for space vehicles are presented. These can be divided into three groups: cold coatings (white paints), middle coatings (aluminum paints) and hot coatings (black paints). Conductive paints, which allow the evacuation of electrostatic charges, and non-conductive paints are considered. Since white conductive paints reduce or cancel the RF transparency a new generation of 'antistatic' white paints was developed to allow electrostatic charge evacuation without reducing RF transparency. A new generation of low outgassing aluminum paints and a new silicone varnish used to protect Kapton against atomic oxygen, are considered. Products under development are discussed. ESA

N94-21401 Nauchno-Proizvodstvennoe Obedinenie Energija, Kaliningrad (USSR).
STUDY OF SPACE FACTORS EFFECT ON MATERIALS FOR SPACECRAFT EXTERNAL SURFACES IN NPO ENERGIA PROGRAMS
V. P. Nikitskiy *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 435-437 (For primary document see N94-21367 05-18)

The purpose and tasks of flight tests in near Earth orbits in the assessment of operating resistance of materials for spacecraft external materials are addressed. They include the determination of the strength and lifetime, verification under the conditions of flight of materials and coatings operationability recommended for perspective space vehicles; investigation of operational characteristics changes (thermal radiational, spectral, physical and mechanical, strength, mass, etc.) after long-term operation; procedures development to forecast materials operating characteristics changes for long-term operation. Specific instruments developed to perform these tests are listed. Different classes of thermal control coatings tested are considered. Experiments showed that the most effective way of material protection from atomic oxygen effect is application to its surfaces of thin coatings based on fluorine plastic materials, metals and silicon oxides. The tests of thermal control coating of the 'solar reflector' class proved their high endurance and allowed to predict their serviceability without further changes of thermal radiation characteristics for orbital service in near Earth orbits for up to 20 to 30 years. A platform, Sinus, developed to continue these experiments is addressed. ESA

COLUMBUS PMP CRITICAL TECHNOLOGIES PROGRAM: APPROACH FOR MATERIALS LIFE TIME PREDICTION
Heinrich Baumann (Erno Raumfahrttechnik G.m.b.H., Bremen, Germany.) and Fabienne Dricot (Erno Raumfahrttechnik G.m.b.H., Bremen, Germany.) *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 441-455 (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

An approach to resolve the verification of materials extended life time behavior for the Columbus elements is described. The combination of the 10 to 30 years life time requirement, on orbit maintenance and repair led to a new strategy in materials selection and verification. This strategy, introduced as the 'PMP (Parts, Materials and Processes) Critical Technologies Program' also considers the schedule and funding constraints which require adaptation to the minimum program needs and pragmatic approaches. TOXICITY OF THERMAL DEGRADATION IN A MANNED SPACE ENVIRONMENT **c54**
M. D. Judd and D. Bryant *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 457-471 (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

An overview of current thinking with regard to flammability and associated hazards pertinent to the special circumstances encountered in a manned space environment is given. The fire performance of materials needs to be assessed on a more comprehensive basis than the past and the first steps to achieving this are presented. More emphasis is necessary on the importance of understanding the toxicity of decomposition products, however difficult this is to quantify in practice. The extra safety problems associated with long term missions in space have to be tackled early in the design stage. The recent decision by the Space Station planners to choose an atmosphere of 30% O2 at 10.7 psi for facilitating EVA (Extravehicular Activity) will undoubtedly lead to a large amount of material testing since most current data is at 24.5% O2 normal pressure. Two research facilities which use a microwave generator to produce high temperature, low pressure, and molecular or dissociated atmospheric conditions for the testing of ceramic materials are presented. These facilities simulate the conditions of atmospheric reentry. One simulator permits the testing of samples of small dimensions (40 by 40 mm) and the other for samples 500 by 500 mm. In the latter the plasma is of the arc blown type. Results of experiments carried out in the small chamber are presented. ESA

A METHOD OF MEASURING THE THERMORADIATIVE PROPERTIES OF CERAMIC MATERIALS IN A SPACE ENVIRONMENT [METHODE DE MESURE DES PROPRIETES THERMORADIATIVES DE MATERIUX CERAMIQUES EN ENVIRONNEMENT SPATIAL] **c27**
M. Balat, C. Dupuy, D. Hernandez, J. F. Robert, and G. Olalde *In* CNES, Fifth International Symposium on Materials in a Space Environment Jun. 1993 p 489-496 In FRENCH (For primary document see N94-21367 05-18)
Copyright Avail: CEPADUES-Editions, 111, rue Nicolas-Vaquelin, 31100 Toulouse, France

A method to measure the thermoradiative properties of ceramic materials to be used for mechanical and thermal protection during reentry is considered. A method to measure emission suitable for space environment simulation devices was developed. A photonic system to measure temperature is described. The operating principle of the experimental device is outlined. Results showed that the emission of the ceramic spacecraft thermal protection materials depends principally on the temperature level, the type of thermal cycle and the surface state of the material, which is itself closely linked to oxidation phenomena at the time of treatment. ESA

Specific test facilities were developed to characterize and validate the performance of thermal protection materials in this particular environment. Two classes of facilities are used: test facilities to determine surface properties which have a direct influence of the temperature of the parts (emissivity, catalycity), and test facilities for simulation of the atmospheric reentry, to study the evolution of materials during this flight phase (plasma torch, radiant facilities). The space plane induced environment is recalled and the operational and under development test facilities are described. Comparative results obtained on reference materials which were tested in those test facilities are presented. The comparative analysis shows a significant difference in behavior, especially in plasma arc jets. Ongoing activities which will be used to identify the most representative facilities are presented. ENTRY VELOCITIES AT MARS AND EARTH FOR SHORT TRANSIT TIMES Final Report, Dec. 1989 - Jul. 1991
Reinald G. Finke Jul. 1993 43 p
(AD-A272591; IDA-P-2602; IDA/HQ-91-37961; AD-E501719) Avail: CASI HC A03/MF A01

Propulsion systems composed of a Shuttle External Tank, appropriately modified for the purpose, with a rocket engine that is either an SSME or a NERVA could inject a gross personnel payload of 100,000 lb on a trans-Mars trajectory from Space Station Freedom with aerobraking at Mars with transit times of less that 70 days. Such transit times reflect a significant reduction from the 200-plus days generally considered. The 100,000-lb payload would include the mass of a hypothetical aerobrake for aerocapture at Mars. The entry velocities at Mars compatible with such transit times are greater that 21 km/sec, to be compared with previously stated constraints of 8.5 to 9.5 km/sec for nominal Mars entry velocity. Limits of current aerobrake technology are not well enough defined to determine the feasibility of an aerobrake to handle Mars-entry velocities for short-transit-time trajectories. Return from Mars to Earth on a mirror image of 70-days outbound trajectory (consistent with a stay time of about 12 days) would require a Mars-departure velocity increment more than twice as great as that at Earth departure and would require a correspondingly more capable propulsion system. The return propulsion system would preferably be pre-deployed at Mars by one or more separate minimum-energy, 0.5 to 1.1 Mlb gross payload cargo flights with the same outbound propulsion systems as the personnel flight, before commitment of the personnel flight. Aerobraking entry velocity at Earth after such a transit time would be about 16 km/sec, to be compared with constraints set at 12.5 to 16 km/sec. DTIC

The purpose is to summarize the spacecraft charging analysis conducted by the plasma interactions group during the period from April 1993 to July 1993, on the proposed TROPIX spacecraft, and to make design recommendations which will limit the detrimental effects introduced by spacecraft charging. The recommendations were presented to the TROPIX study team at a Technical Review meeting held on 15 July 1993.

[A NEW INNOVATIVE INSTRUMENT FOR SPACE PLASMA INSTRUMENTATION] Final Report
Roy B. Torbert 6 Dec. 1993 50 p
(Grant NAGw-2043)
(NASA-CR-194736; NAS 1.26:194736) Avail: CASI HC A03/MF A01

The Faraday Ring Ammeter was the subject of this grant for a new innovative instrument for space plasma instrumentation. This report summarizes our progress in this work. Briefly, we have conducted an intensive series of experiments and trials over three years, testing some five configurations of the instrument to measure currents, resulting in two Ph.D. theses, supported by this grant, and two flight configurations of the instrument. The first flight would have been on a NASA-Air Force collaborative sounding rocket, but was not flown because of instrumental difficulties. The second has been successfully integrated on the NASA Auroral Turbulence payload which is to be launched in February, 1994.

The purpose of this standard is to provide an umbrella set of requirements for applying the generic architecture interface model to the design of a specific avionics hardware/software system. This standard defines a generic set of system interface points to facilitate identification of critical interfaces and establishes the requirements for applying appropriate low level detailed implementation standards to those interface points. The generic core avionics system and processing architecture models provided herein are robustly tailorable to specific system applications and provide a platform upon which the interface model is to be applied.

The final report describes the combined work of the Computational Chemistry and Aerothermodynamics branches within the Thermosciences Division at NASA Ames Research Center directed at understanding the signatures of shock-heated air. Considerable progress was made in determining accurate transition probabilities for the important band systems of NO that account for much of the emission in the ultraviolet region. Research carried out under this project showed that in order to reproduce the observed radiation from the bow shock region of missiles in their boost phase it is necessary to include the Burnett terms in the constituent equation, account for the non-Boltzmann energy distribution, correctly model the NO formation and rotational excitation process, and use accurate

transition probabilities for the NO band systems. This work resulted in significant improvements in the computer code NEQAIR that models both the radiation and fluid dynamics in the shock region. DTIC

INVESTIGATION OF FLAME DRIVING AND FLOW TURNING IN AXIAL SOLID ROCKET INSTABILITIES Final Report, 1 Mar. 1991 - 30 Jun. 1993
Ben T. Zinn, Brady R. Daniel, and Lawrence M. Matta 31 Aug. 1993 78 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0160-91)
(AD-A271066; AFOSR-93-0776TR) Avail: CASI HC A05

An understanding of the processes responsible for driving and damping acoustic oscillations in solid rocket motors is necessary for developing practical design methods that eliminate or reduce the occurrence combustion instabilities. While state of the art solid rocket stability prediction methods generally account for the flow turning loss, the magnitude and characteristics of this loss have never been fully investigated. Results of an investigation of the role of the flow turning loss in the stability of solid rockets and its dependence upon motor design and operating parameters are described. A one dimensional acoustic stability equation that verifies that the flow turning loss term is appropriately included in the one dimensional stability formulation was derived for a chamber with a constant mean temperature and pressure by an approach independent from that of Culick. This study was extended providing the background and expressions needed to guide an experimental study of the flow turning loss in the presence of mean temperature and density gradients. This allows the study of combustion systems in which mean temperature gradients and heat losses are significant. The relevant conservation equations were solved numerically for the experimental configuration in order to predict the behavior of the flow turning loss and to assist in the analysis of experimental results. Experiments performed, with and without combustion, showed that the flow turning loss strongly depends upon the propellant burning rate and the location of the flow turning region relative to the standing pressure wave. SYSTEM PERFORMANCE PREDICTIONS FOR SPACE STATION FREEDOM'S ELECTRIC POWER SYSTEM
Thomas W. Kerslake, Jeffrey S. Hojnicki, Robert D. Green, and Jeffrey C. Follo Nov. 1993 8 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993; sponsored by American Chemical Society
(RTOP 474-12-10)
(NASA-TM-106396; E-8221; NAS 1.15:106396) Avail: CASI HC A02/MF A01

Space Station Freedom Electric Power System (EPS) capability to effectively deliver power to housekeeping and user loads continues to strongly influence Freedom's design and planned approaches for assembly and operations. The EPS design consists of silicon photovoltaic (PV) arrays, nickel-hydrogen batteries, and direct current power management and distribution hardware and cabling. To properly characterize the inherent EPS design capability, detailed system performance analyses must be performed for early stages as well as for the fully assembled station up to 15 years after beginning of life. Such analyses were repeatedly performed using the FORTRAN code SPACE (Station Power Analysis for Capability Evaluation) developed at the NASA Lewis Research Center over a 10-year period. SPACE combines orbital mechanics routines, station orientation/pointing routines, PV array and battery performance models, and a distribution system load-flow analysis to predict EPS performance. Time-dependent, performance degradation, low earth orbit environmental interactions, and EPS architecture build-up are incorporated in SPACE. Results from two typical SPACE analytical cases are presented: (1) an electric load driven case and (2) a maximum EPS capability case. Author

The principles of rocket propulsion and the advantages of the different schemes and propellant combinations are reviewed. The aim was to focus on the cryogenic types of propulsion units and the cycles on which they were based. A general overview of the main current engines is given. Specific items of propulsion or turbomachinery nature are included. The prospects of future applications are covered. The large cryogenic rocket engines and typical examples of the different cycles used in the design of advanced units currently in operation are summarized. Special turbomachinery problems such as the pump and turbine drive designs with their typical problems in the cryogenic environment are considered. Turbine nozzle and bucket design were reviewed. The high performance pump was exposed to the cavitation problems and an advanced analysis for the loss model was required using the distributed loss concept. For individual titles, see N94-20069 through N94-20080.

LIQUID ROCKET PROPULSION. THEORY
M. Martinez-Sanchez *In* VKI, Spacecraft Propulsion 1993 105 p (For primary document see N94-20068 05-20)
Copyright Avail: CASI HC A06/MF A04

The purpose is to introduce the fundamentals and the basic technology of liquid propellant rockets. Much of the material is derived from other courses on propulsion. The first lecture covers the foundations at the broad brush level. Starting from the functional requirements placed on the device, various types of rocket are examined. The missions for which liquid propellant rockets are the better choice are identified. An ideal gas examination of the essential performance parameters and their variation with basic controllable inputs is presented. The thermodynamics and the fluid mechanics of the reacting flows occurring in rocket combustors and nozzles are considered. The effects of propellant choices and the +/- 5 performance estimates are included. ESA

ROCKETDYNE TURBOMACHINERY
Eugene D. Jackson *In* VKI, Spacecraft Propulsion 1993 19 p (For primary document see N94-20068 05-20)
Copyright Avail: CASI HC A03/MF A04

The four turbopumps used on the Space Shuttle Main Engine (SSME) highlighting key features of each, are described. The historical development

of liquid rocket engine turbopumps primarily using those from Rocketdyne as representatives is reviewed. The design of the SSME turbopumps required significantly extending the range of operation of key turbopump parameters. The SSME was the first staged combustion cycle, first reusable engine, and the turbopumps operated at much higher power densities, pressure levels, and speeds. Through the design process, the technical level of analysis had to be increased to handle the increased power densities and pressures and to address the longer life issues. The SSME turbopumps have not only achieved their mission of successfully performing on all flights to date but also have led to the state of the art technology that is applied to new turbopump designs today. ESA

FUTURE TECHNICAL DIRECTIONS

Eugene D. Jackson and Munir Sindir *In* VKI, Spacecraft Propulsion 1993 20 p (For primary document see N94-20068 05-20)

Copyright Avail: CASI HC A03/MF A04

The areas of more recent technical advances are discussed. These are necessarily limited to those areas approved for public dissemination. The presentation is organized as follows: new directions in the Space Shuttle Main Engine (SSME); Computational Fluid Dynamics (CFD) advances; and other areas of technology advances. The advances in the SSME are focused on the continued support to reliable flights with additional benefits in lower cost and improved robustness. In the area of CFD, significant advances are made and emphasis is placed on further reductions in time and cost to perform the complex CFD in product design organizations. The need to better understand and analyze the reality of the environments and products that are designed are discussed. This includes emphasis on dynamic loads; probabilistic as well as deterministic loads, material properties, and hardware variations; and such real property effects as the existence of flaws. Each area represents significant challenges to the engineer of the future. ESA

The purpose of liquefaction is considered. The cooling processes of a gas and of a liquid are reviewed. The importance of heat conduction and radiation in the storage of cryogenic liquids is discussed. The properties of the following cryogenic liquids are summarized: oxygen, nitrogen, hydrogen, 4-helium, and 3-helium. Data on boiling points, heat of vaporization and density is given. ESA

A TUTORIAL ON THE AERO/THERMODYNAMICAL DESIGN OF LIQUID-PROPELLANT ROCKET ENGINE NOZZLES

Lars-Olaf Pekkari *In* VKI, Spacecraft Propulsion 1993 18 p (For primary document see N94-20068 05-20)

Copyright Avail: CASI HC A03/MF A04

The most basic aspects in the design of nozzles for liquid propellant rocket engines are presented. First the divergence loss and the optimizing of the nozzle contour are described. Second the flow separation and performance of sea level nozzles are discussed. Alternative sea level nozzle concepts are outlined. The heat transfer and basic concepts for the cooling of nozzles are presented. The tutorial examples are based on the simplest methods applicable to get a transparent description of each subject. Turbines for most space propulsion applications, such as the hydrogen and oxygen pump turbines for the Vulcain engine, are characterized by a high pressure ratio, a highly energetic working fluid, and a small size. Data on Vulcain turbines are given. The following topics are reviewed: turbine concept design and design tools; blade design; losses occurring in a blade which are due to friction, secondary flow, tip clearance and shock formation; and turbine testing. The purpose of any turbine is to provide power for other parts of an engineering system (compressors, electrical generators, pumps) or to drive mechanical components such as wheels or propellers to give propulsion to a vehicle. It should therefore always be the performance and cost effectiveness of this larger system and not of the isolated turbine that are the main objectives for the turbine design engineer. ESA

Modern achievements and the problems of powerful Liquid Rocket Engines (LRE) for launch system main propulsion units are shown. Results of LRE research and development carried out in Russia are included. LRE's have been used since the beginning of the forties. Many investigations were carried out on the design of high efficiency LRE's and the technology for engine development and production. Recent data and technology have led to the development of LRE's which have parameters that are close to the upper design limits. ESA

The Ariane 5 was developed for the purpose of serving as the next generation Ariane launcher. The Ariane 5 main stage is powered by the Vulcain cryogenic engine. The engine operation, its main technical characteristics, and its development activities are described. The features present due to the use of liquid oxygen and, especially, liquid hydrogen are emphasized: start up procedures; ignition of the combustion; materials; mastering liquid hydrogen leakages; and safety studies. A brief development status is given. 440 engines tests and more than 100,000 seconds are planned before the end of the development to ensure reliability and safety. ESA

DISTRIBUTED LOSS MODEL: APPLICATION TO A SPATIAL TURBOPUMP INDUCER

E. M. ElGhazzani, G. Bois, and F. Leboeuf (Ecole Centrale de Lyon, France.) *In* VKI, Spacecraft Propulsion 1993 51 p (For primary document see N94-20068 05-20)

Copyright Avail: CASI HC A04/MF A04

A three dimensional Euler flow computation in a spatial turbopump inducer with a distributed loss model at nominal flow rate is presented. The numerical results and the experimental ones are in good agreement. The loss model described uses a simple pitch averaged distribution of rotary stagnation pressure drop between hub and tip. A finely distributed loss model which can take into account global losses such as the effects of boundary layer on blades and the clearance gap ones is considered. Particular treatment of boundary conditions to simulate the rotation of the tip end wall is presented. One of the particularities of this method is to simulate back flow. The code CALECHE and the Clebsch-Hawthorne formulation are used. This code is also performed on a variety of isolate blade rows. ESA

CAVITATION MODELLING

J. L. Kueny *In* VKI, Spacecraft Propulsion 1993 26 p (For primary document see N94-20068 05-20)

Copyright Avail: CASI HC A03/MF A04

Improvements of cavitation modeling during the past years are reviewed. They are directly correlated to the development of the computers and above all to the development of cryogenic liquid propellant fed rocket engines. Cavitation is the evaporation of a liquid, caused by lowering its pressure. It occurs at locations where the pressure falls short of a critical value, roughly corresponding to the vapor pressure. In these areas of lowest pressure, vaporous cavities appear, that rest on walls or float within the liquid. New models are available for calculation of three dimensional

partial cavitation in pumps with steady state assumptions. Two dimensional unsteady cavitating flow modelization are in development. Promising results are obtained for the prediction of the thermodynamical effects on cavitation by using a coupled code of the external liquid and the internal vapor flow. ESA

THREE DIMENSIONAL UNSTEADY FLOW CALCULATIONS IN RADIAL COMPONENTS **c34**

A. Fatsis *In its* Spacecraft Propulsion 1993 53 p (For primary document see N94-20068 05-20)

Copyright Avail: CASI HC A04/MF A04

A numerical model to predict the impeller response due to the downstream static pressure distortion caused by the volute when a centrifugal compressor works at off design conditions is presented. The three dimensional Euler equations are solved by a time marching technique allowing the evaluation of the unsteady flowfield using the finite volume space discretization and Runge-Kutta time stepping scheme. Phase lagged periodicity conditions were used in the computations of the unsteady flow upstream and downstream the blade channel. Reflecting and non-reflecting boundary conditions were tested. It was demonstrated that the latter result in faster convergence than the former. A cyclic variation of the impeller flowfield due to the donwstream static pressure non-uniform distribution is observed. ESA

The possibility of beaming power from synchronous lunar orbits (the L1 and L2 Lagrange points) to a manned long-range lunar rover is addressed. The rover and two versions of a satellite system (one powered by a nuclear reactor, the other by photovoltaics) are described in terms of their masses, geometries, power needs, missions, and technological capabilities. Laser beam power is generated by a laser diode array in the satellite and converted to 30 kW of electrical power at the rover. Present technological capabilities, with some extrapolation to near future capabilities, are used in the descriptions. The advantages of the two satellite/rover systems over other such systems and over rovers with onboard power are discussed along with the possibility of enabling other missions. Author (revised)

ROCKETS: PHYSICAL SCIENCE TEACHER'S GUIDE WITH ACTIVITIES

Gregory L. Vogt (National Aeronautics and Space Administration. Lyndon B. Johnson Space Center, Houston, TX.) and Carla R. Rosenberg, ed. Jul. 1993 47 p

(NASA-EP-291; NAS 1.19:291) Avail: CASI HC A03/MF A01

This guide begins with background information sections on the history of rocketry, scientific principles, and practical rocketry. The sections on scientific principles and practical rocketry are based on Isaac Newton's three laws of motion. These laws explain why rockets work and how to make them more efficient. The background sections are followed with a series of physical science activities that demonstrate the basic science of rocketry. Each activity is designed to be simple and take advantage of inexpensive materials. Construction diagrams, materials and tools lists, and instructions are included. A brief discussion elaborates on the concepts covered in the activities and is followed with teaching notes and discussion questions. The guide concludes with a glossary of terms, suggested reading list, NASA educational resources, and an evaluation questionnaire with a mailer. Derived from text

LIQUID FUEL INJECTION ELEMENTS FOR ROCKET ENGINES Patent

George B. Cox, Jr., inventor (to NASA) 30 Nov. 1993 7 p Filed 27 Jan. 1993 Supersedes N93-29847 (31 - 11, p 3289)

(NASA-Case-MFS-28547-1; US-Patent-5,265,415; US-Patent-Appl-SN-010037; US-Patent-Class-60-258; US-Patent-Class-60-741; US-Patent-Class-137-853; US-Patent-Class-137-855; US-Patent-Class-239-410; US-Patent-Class-239-533.2; Int-Patent-Class-F02K-9/00) Avail: US Patent and Trademark Office

Thrust chambers for liquid propellant rocket engines include three principal components. One of these components is an injector which contains a plurality of injection elements to meter the flow of propellants at a predetermined rate, and fuel to oxidizer mixture ratio, to introduce the mixture into the combustion chamber, and to cause them to be atomized within the combustion chamber so that even combustion takes place. Evolving from these injectors are tube injectors. These tube injectors have injection elements for injecting the oxidizer into the combustion chamber. The oxidizer and fuel must be metered at predetermined rates and mixture ratios in order to mix them within the combustion chamber so that combustion takes place smoothly and completely. Hence tube injectors are subject to improvement. An injection element for a liquid propellant rocket engine of the bipropellant type is provided which includes tangential fuel metering orifices, and a plurality of oxidizer tube injection elements whose injection tubes are also provided with tangential oxidizer entry slots and internal reed valves. (NASA-Case-NPO-18192-1-CU; US-Patent-5,269,131;

US-Patent-Appl-SN-934988; US-Patent-Class-60-202;
Int-Patent-Class-H05H-1/00) Avail: US Patent and Trademark Office

Apparatus and methods for large-area, high-power ion engines comprise dividing a single engine into a combination of smaller discharge chambers (or segments) configured to operate as a single large-area engine. This segmented ion thruster (SIT) approach enables the development of 100-kW class argon ion engines for operation at a specific impulse of 10,000 s. A combination of six 30-cm diameter ion chambers operating as a single engine can process over 100 kW. Such a segmented ion engine can be operated from a single power processor unit.

DUAL-BEAM MULTIPLE WAVELENGTH LIGHT TRANSMITTANCE MEASUREMENT FOR PARTICLE SIZING IN ROCKET MOTOR PLUMES M.S. Thesis
Kevin B. Taylor Jun. 1993 49 p
(AD-A272491) Avail: CASI HC A03/MF A01

A multiple-wavelength light transmittance measurement system previously used in a laboratory environment to study particles in solid rocket propellant exhaust plumes was modified for use in the field, where high levels of vibration can degrade the accuracy of data. The system was converted from a single light beam configuration to a dual beam configuration which was capable of obtaining a complete set of 1024 reference and scene measurements in 10.0 ms. Modifications included designing, building and testing a new analog-to-digital data converter trigger circuit, and a rotating-wheel light chopper. Optical components including beam splitters, lenses, and a fiber optic cable were installed, and existing data collection system software was modified. The new system was tested by measuring soot from an oxyacetylene torch to prove the design concept. Test results and system performance were documented. Recommendations for further modifications, improvements and applications are presented. DTIC

ADVANCED TRANSPORTATION SYSTEM STUDIES, TECHNICAL AREA 3. ALTERNATE PROPULSION SUBSYSTEM CONCEPTS: J-2S RESTART STUDY Final Report, Sep. 1992 - Apr. 1993
John Vilja and Daniel Levack Apr. 1993 179 p
(Contract NAS8-39210)
(NASA-CR-193874; NAS 1.26:193874; DCN-1-1-PP-02147) Avail: CASI HC A09/MF A02

The objectives were to assess what design changes would be required to remit late production of the J-2S engine for use as a large high energy upper stage engine. The study assessed design changes required to perform per the J-2S model specification, manufacturing changes required due to obsolescence or improvements in state-of-the-practice, availability issues for supplier provided items, and provided cost and schedule estimates for this configuration. The confidence that J-2S production could be reinitiated within reasonable costs and schedules was provided. No significant technical issues were identified in either the producibility study or in the review of previous technical data. Areas of potential cost reduction were identified which could be quantified to a greater extent with further manufacturing planning. The proposed schedule can be met with no foreseeable impacts. The results of the study provided the necessary foundation for the detailed manufacturing and test plans and non-recurring and recurring cost estimates that are needed to complete the effort to reinitiate production of the J-2S engine system. EVALUATION OF EXTERNALLY HEATED PULSED MPD THRUSTER CATHODES Final Report
Roger M. Myers, Matthew Domonkos (New Mexico Univ., Albuquerque.), and Alec D. Gallimore (Michigan Univ., Ann Arbor.) Dec. 1993 14 p
Presented at the 23rd International Electric Propulsion Conference, Seattle, WA, 13-16 Sep. 1993; sponsored by AIAA
(Contract NAS3-25266; RTOP 506-42-31)
(NASA-CR-191090; E-8293; NAS 1.26:191090) Avail: CASI HC A03/MF A01

Recent interest in solar electric orbit transfer vehicles (SEOTV's) has prompted a reevaluation of pulsed magnetoplasmadynamic (MPD) thruster systems due to their ease of power scaling and reduced test facility requirements. In this work the use of externally heated cathodes was examined in order to extend the lifetime of these thrusters to the 1000 to 3000 hours required for SEOTV missions. A pulsed MPD thruster test facility was assembled, including a pulse-forming network (PFN), ignitor supply and propellant feed system. Results of cold cathode tests used to validate the facility, PFN, and propellant feed system design are presented, as well as a preliminary evaluation of externally heated impregnated tungsten cathodes. The cold cathode thruster was operated on both argon and nitrogen propellants at peak discharge power levels up to 300 kW. The results confirmed proper operation of the pulsed thruster test facility, and indicated that large amounts of gas were evolved from the BaO-CaO-Al2O3 cathodes during activation. Comparison of the expected space charge limited current with the measured vacuum current when using the heated cathode indicate that either that a large temperature difference existed between the heater and the cathode or that the surface work function was higher than expected. PRELIMINARY SP-100/STIRLING HEAT EXCHANGER DESIGNS
Paul Schmitz (Sverdrup Technology, Inc., Brook Park, OH.), Leonard Tower (Sverdrup Technology, Inc., Brook Park, OH.), Ronald Dawson (Aerospace Design and Fabrication, Inc., Brook Park, OH.), Brian Blue, and Pat Dunn Dec. 1993 11 p Proposed for presentation at the Eleventh Symposium on Space Nuclear Power and Propulsion, Albuquerque, NM, 10-14 Jan. 1994; sponsored by the Inst. for Space Nuclear Studies and ANS
(Contract NAS3-25266; RTOP 583-02-21)
(NASA-TM-106444; E-8288; NAS 1.15:106444) Avail: CASI HC A03/MF A01

Analytic modeling of several heat exchanger concepts to couple the SP-100 nuclear reactor primary lithium loop and the Space Stirling Power Convertor (SSPC) was performed. Four 25 kWe SSPC's are used to produce the required 100 kW of electrical power. This design work focused on the interface between a single SSPC and the primary lithium loop. Manifolding to separate and collect the four channel flow was not modeled. This work modeled two separate types of heat exchanger interfaces (conductive coupling and radiative coupling) to explore their relative advantages and disadvantages. The minimum mass design of the conductively coupled concepts was 18 kg or 0.73 kg/kWe for a single 25 kWe convertor. The minimum mass radiatively coupled concept was 41 kg or 1.64 kg/kWe. The direct conduction heat exchanger provides a lighter weight system because of its ability to operate the Stirling convertor evaporator at higher heat fluxes than those attainable by the radiatively coupled systems. Additionally the conductively coupled concepts had relatively small volumes and provide potentially simpler assembly. Their disadvantages were the tight tolerances and material joining problems associated with this refractory to superalloy interface. The advantages of the radiatively coupled designs were the minimal material interface problems. Author

SPACE-R THERMIONIC SPACE NUCLEAR POWER SYSTEM: DESIGN AND TECHNOLOGY DEMONSTRATION PROGRAM
May 1993 298 p
(Contract DE-AC03-92SF-19441)
(DE93-013969; DOE/SF-19441/T4) Avail: CASI HC A13/MF A03

This semiannual technical progress report summarizes the technical progress and accomplishments for the Thermionic Space Nuclear Power System (TI-SNPS) Design and Technology Demonstration Program of the prime contractor, Space Power Incorporated (SPI), its subcontractors, and supporting national laboratories during the first half of the government fiscal year (GFY) 1993. SPI's subcontractors and supporting national laboratories include: Babcock & Wilcox for the reactor core and externals; Space Systems/Loral for the spacecraft integration; Thermocore for the radiator heat pipes and the heat exchanger; INERTEK of CIS for the TFE, core elements, and nuclear tests; Argonne National Laboratories for nuclear safety, physics, and control verification; and Oak Ridge National laboratories for materials testing. Parametric trade studies are near completion. However, technical input from INERTEK has yet to be provided to determine some of the baseline design configurations. The INERTEK subcontract is expected to be initiated soon. The point design task has been initiated. The thermionic fuel element (TFE) is undergoing several design iterations. The reactor core vessel analysis and design has also been started. DOE

PERFORMANCE ASSESSMENT OF LOW PRESSURE NUCLEAR THERMAL PROPULSION

H. P. Gerrish, Jr. and G. E. Doughty Dec. 1993 24 p

(NASA-TM-108433; NAS 1.15:108433) Avail: CASI HC A03/MF A01

A low pressure nuclear thermal propulsion (LPNTP) system, which takes advantage of hydrogen dissociation/recombination, was proposed as a means of increasing engine specific impulse (Isp). The effect of hydrogen dissociation/recombination on LPNTP Isp is examined. A two-dimensional computer model was used to show that the optimum chamber pressure is approximately 100 psia (at a chamber temperature of 3,000 K), with an Isp approximately 15 s higher than at 1,000 psia. At high chamber temperatures and low chamber pressures, the increase in Isp is due to both lower average molecular weights caused by dissociation and added kinetic energy from monatomic hydrogen recombination. Monatomic hydrogen recombination increases the Isp more then hydrogen dissociation. Variations in the mole fraction of monatomic hydrogen are similar to variations in static pressure along the axial nozzle position. Most recombination occurs close to the nozzle throat. Practical variations in nozzle geometry have minimal impact on recombination. Other models which can simulate a wider range of nozzle designs should be used in the future. The uncertainty of the hydrogen kinetic reaction rates at high temperatures (approximately 3,000 K) affects the accuracy of the analysis and should be verified with simple bench tests. BRAYTON POWER CONVERSION SYSTEM PARAMETRIC DESIGN MODELLING FOR NUCLEAR ELECTRIC PROPULSION Final Report

Thomas L. Ashe (Allied-Signal Aerospace Co., Tempe, AZ.) and William D. Otting 21 Nov. 1993 160 p

(Contract NAS3-25808; RTOP 593-72-00)

(NASA-CR-191135; NAS 1.26:191135; Rept-93RC-010143) Avail: CASI HC A08/MF A02

The parametrically based closed Brayton cycle (CBC) computer design model was developed for inclusion into the NASA LeRC overall Nuclear Electric Propulsion (NEP) end-to-end systems model. The code is intended to provide greater depth to the NEP system modeling which is required to more accurately predict the impact of specific technology on system performance. The CBC model is parametrically based to allow for conducting detailed optimization studies and to provide for easy integration into an overall optimizer driver routine. The power conversion model includes the modeling of the turbines, alternators, compressors, ducting, and heat exchangers (hot-side heat exchanger and recuperator). The code predicts performance to significant detail. The system characteristics determined include estimates of mass, efficiency, and the characteristic dimensions of the major power conversion system components. These characteristics are parametrically modeled as a function of input parameters such as the aerodynamic configuration (axial or radial), turbine inlet temperature, cycle temperature ratio, power level, lifetime, materials, and redundancy. (NASA-CR-194716; NAS 1.26:194716) Avail: CASI HC A04/MF A01

The overall goal of this research effort has been the development of a software system which automates tasks related to monitoring and controlling electrical power distribution in spacecraft electrical power systems. The resulting software system is called the Intelligent Power Controller (IPC). The specific tasks performed by the IPC include continuous monitoring of the flow of power from a source to a set of loads, fast detection of anomalous behavior indicating a fault to one of the components of the distribution systems, generation of diagnosis (explanation) of anomalous behavior, isolation of faulty object from remainder of system, and maintenance of flow of power to critical loads and systems (e.g. life-support) despite fault conditions being present (recovery). The IPC system has evolved out of KATE (Knowledge-based Autonomous Test Engineer), developed at NASA-KSC. KATE consists of a set of software tools for developing and applying structure and behavior models to monitoring, diagnostic, and control applications. Author

(NASA-CR-194721-Vol-1; NAS 1.26:194721-Vol-1) Avail: CASI HC A04/MF A01

Over the past year, the Propulsion Engineering Research Center at The Pennsylvania State University continued its progress toward meeting the goals of NASA's University Space Engineering Research Centers (USERC) program. The USERC program was initiated in 1988 by the Office of Aeronautics and Space Technology to provide an invigorating force to drive technology advancements in the U.S. space industry. The Propulsion Center's role in this effort is to provide a fundamental basis from which the technology advances in propulsion can be derived. To fulfill this role, an integrated program was developed that focuses research efforts on key technical areas, provides students with a broad education in traditional propulsion-related science and engineering disciplines, and provides minority and other under-represented students with opportunities to take their first step toward professional careers in propulsion engineering. The program is made efficient by incorporating government propulsion laboratories and the U.S. propulsion industry into the program through extensive interactions and research involvement. The Center is comprised of faculty, professional staff, and graduate and undergraduate students working on a broad spectrum of research issues related to propulsion. The Center's research focus encompasses both current and advanced propulsion concepts for space transportation, with a research emphasis on liquid propellant rocket engines. The liquid rocket engine research includes programs in combustion and turbomachinery. Other space transportation modes that are being addressed include anti-matter, electric, nuclear, and solid propellant propulsion. Outside funding supports a significant fraction of Center research, with the major portion of the basic USERC grant being used for graduate student support and recruitment. The remainder of the USERC funds are used to support programs to increase minority student enrollment in engineering, to maintain Center infrastructure, and to develop research capability in key new areas. Significant research programs in propulsion systems for air and land transportation complement the space propulsion focus. The primary mission of the Center is student education. The student program emphasizes formal class work and research in classical engineering and science disciplines with applications to propulsion. Author (revised)

(NASA-Case-LAR-14606-1-CU; US-Patent-5,270,432; US-Patent-Appl-SN-867864; US-Patent-Class-528-128; US-Patent-Class-528-125; US-Patent-Class-528-126; US-Patent-Class-528-167; US-Patent-Class-528-171; US-Patent-Class-528-172; US-Patent-Class-528-174) Avail: US Patent and Trademark Office

Polybenzoxazoles (PBO) are heterocyclic macromolecules which were first synthesized in a two-step process by the initial formation of aromatic diacid chlorides with bis(o-aminophenol)s through solution condensation of aromatic diacid chlorides with bis(o-aminophenol)s followed by thermal cyclodehydration. Since then several methods were utilized in their synthesis. The most common synthetic method for PBO involves a polycondensation of bis(o-aminophenol)s with aromatic diacid diphenyl esters. Another preparative route involves the solution polycondensation of the hydrochloride salts of bis(o-amino phenol)s with aromatic diacids in polyphosphoric acid. Another synthetic method involves the initial formation of poly(o-hydroxy amide)s from silylated bis(o-aminophenol)s with aromatic diacid chlorides followed by thermal cyclodehydration to PBO. A recent preparative route involves the reaction of aromatic bisphenols with bis(fluorophenyl) benzoxazoles by the displacement reaction to form PBO. The novelty of the present invention is that high molecular weight PBO of new chemical structures are prepared that exhibit a favorable combination of physical and mechanical properties.

QUANTITATIVE EVALUATION OF MATERIAL COMPOSITION OF COMPOSITES USING X RAY ENERGY-DISPERSIVE NDE TECHNIQUE Ph.D. Thesis
J. Ting 1 Sep. 1993 97 p
(Contract W-7405-eng-82)
(DE93-041157; IS-T-1640) Avail: CASI HC A05/MF A02

The technique described in this paper works well for determining the thickness and density of composite components having the higher linear attenuation coefficient; it accurately determines the thickness of epoxy-resin and Al metal, and the density of bone, to less than or equal to 4% in the graphite-epoxy, bone-plexiglass, and Al-Al corrosion composites. Accuracy is dictated by the magnitude and uncertainty of the linear attenuation coefficient. Use of Ge detector and multichannel analyzer is limited by inspection time (1 day for point measurement) and access limitation. Immediate development of a rapid in-service inspection tool is limited by the amplifier and MCA systems. The MCA should be replaced with a single-channel analyzer, and an electronic device should be built for monitoring the incoming signal for pile-up-rejection. DOE

PHTHALONITRILE PREPOLYMER AS HIGH TEMPERATURE SIZING MATERIAL FOR COMPOSITE FIBERS Patent Application
Teddy M. Keller, inventor (to Navy) 28 Jun. 1993 21 p
(AD-D015912; US-Patent-Appl-SN-082645; Navy-Case-74791) Avail: CASI HC A03/MF A01

Sized fibers, for use as reinforcements in high temperature polymeric composites, are prepared by coating the outside surface of the fibers with an amorphous, B-stage bisphthalonitrile prepolymer. The prepolymer may be prepared by curing a bisphthalonitrile monomer with an organic amine, an aromatic organic acid, a mineral acid, a Lewis acid or a salt of any of the above. Then, the fibers are coated by passage through an organic solution of the prepolymer. Either before or after completely curing the prepolymer coating on the fibers, the coated fibers are covered with a resin, for example, by passage through a solution or melt of a polyimide or bisphthalonitrile resin. If the phthalonitrile coating was incompletely cured prior to covering the phthalonitrile-coated fiber with the resin, the heat during the subsequent cure of the resin also completely cures the phthalonitrile coating. The resulting composite has excellent high temperature properties. In a preferred embodiment, the coated fibers are used to form a prepreg for usage in composite fabrication. DTIC

METAL-GLASS COMPOSITE FIELD-EMITTING ARRAYS Patent
Jack D. Ayers, inventor (to Navy) 13 Apr. 1993 7 p Filed 10 Dec. 1991
(AD-D015942; US-Patent-5,202,602; US-Patent-Appl-SN-804558; US-Patent-Class-313-309) Avail: US Patent and Trademark Office

A field-emitting array is provided which comprises at least one thin wafer having electrically conducting filaments extending through a glass matrix between a first and second parallel surface of the wafer. At the first surface, the filaments extend beyond the plane of the glass matrix. The filaments extending beyond the first surface have an electron-emitting coating on their cylindrical surfaces. The coating extends beyond the filament end to create a shape that emits electrons when an electrical field is applied between the filaments and an anode. In an alternative embodiment, the filaments are recessed below the first surface and a conducting coating forms an extractor on that surface. DTIC

STRUCTURAL SIMILITUDE AND DESIGN OF SCALED DOWN LAMINATED MODELS
G. J. Simitses and J. Rezaeepazhand Dec. 1993 40 p
(Grant NAG1-1280)
(NASA-CR-194687; NAS 1.26:194687) Avail: CASI HC A03/MF A01

The excellent mechanical properties of laminated composite structures make them prime candidates for wide variety of applications in aerospace, mechanical and other branches of engineering. The enormous design flexibility of advanced composites is obtained at the cost of large number of design parameters. Due to complexity of the systems and lack of complete design based informations, designers tend to be conservative in their design. Furthermore, any new design is extensively evaluated experimentally until it achieves the necessary reliability, performance and safety. However, the experimental evaluation of composite structures are costly and time consuming. Consequently, it is extremely useful if a full-scale structure can be replaced by a similar scaled-down model which is much easier to work with. Furthermore, a dramatic reduction in cost and time can be achieved, if available experimental data of a specific structure can be used to predict the behavior of a group of similar systems. This study investigates problems associated with the design of scaled models. Such study is important since it provides the necessary scaling laws, and the factors which affect the accuracy of the scale models. Similitude theory is employed to develop the necessary similarity conditions (scaling laws). Scaling laws provide relationship between a full-scale structure and its scale model, and can be used to extrapolate the experimental data of a small, inexpensive, and testable model into design information for a large prototype. Due to large number of design parameters, the identification of the principal scaling laws by conventional method (dimensional analysis) is tedious. Similitude theory based on governing equations of the structural system is more direct and simpler in execution. The difficulty of making completely similar scale models often leads to accept certain type of distortion from exact duplication of the prototype (partial similarity). Both complete and partial similarity are discussed. The procedure consists of systematically observing the effect of each parameter and corresponding scaling laws. Then acceptable intervals and limitations for these parameters and scaling laws are discussed. In each case, a set of valid scaling factors and corresponding response scaling laws that accurately predict the response of prototypes from experimental models is introduced. The examples used include rectangular laminated plates under destabilizing loads, applied individually, vibrational characteristics of same plates, as well as cylindrical bending of beam-plates. DEVELOPMENT OF BIOELASTIC MATERIAL FOR ASPECTS OF WOUND REPAIR Training Progress Report, Jan. - Apr. 1993
Apr. 1993 5 p
(Contract N00014-90-C-0265)
(AD-A267832) Avail: CASI HC A01/MF A01

The broad goal of this contract is the synthesis and characterization of bioelastic materials designed for specific applications of wound healing. Specifically, for materials with possible use as wound coverings, control of the temperature of transition by changes in hydrophobicity will be examined. In addition, the rate of water passage through the matrix will be determined. The first application phase was concerned primarily with synthesis of the basic poly pentapeptide poly (VPGVG) and the analog with L-alanine substituted in position 3,poly (VPAVG) and mole fraction combinations thereof to achieve elastomeric matrices of varying elastic moduli. In the third year, poly pentapeptides containing chemical clocks are to be characterized for their rate of breakdown and their effects on drug release profiles. This document presents the goals, progress, and future plans of the current contract. Progress reported includes the transition temperatures of two bioelastic polymers and stress-strain curves for two matrices. CASI

THE EFFECTS OF PROCESSING AND CONSTITUENT MATERIALS ON COMPRESSIVE STRENGTH OF THICK COMPOSITE LAMINATES Annual Report
H. T. Hahn, E. A. Kempner, and J. Slaughter Aug. 1993 42 p
(Contract N00014-92-J-1846)
(AD-A271912) Avail: CASI HC A03/MF A01

The objectives of this study pertain to both the processing of thick composites and the constituent materials used. The main objectives of the research are to identify the processing conditions that are responsible for fiber wrinkling in thick, filament-wound cylinders and to develop a process simulation model for filament winding of thick cylinders. Analysis-experiment correlation will be used to aid model development. Also, the effect of constituent materials on compressive strength will be studied. This will be accomplished by identifying the fiber microstructure responsible for low compressive strength and developing an analytical model relating fiber microstructure to compressive strength. INTERCALATED HYBRID GRAPHITE FIBER COMPOSITE Patent
James R. Gaier, inventor (to NASA) 9 Nov. 1993 6 p Filed 25 Nov. 1991 Supersedes N92-17861 (30 - 8, p 1257)
(NASA-Case-LEW-15241-1; US-Patent-5,260,124; US-Patent-Appl-SN-798464; US-Patent-Class-428-257; US-Patent-Class-244-1A; US-Patent-Class-361-218; US-Patent-Class-428-260; US-Patent-Class-428-288; US-Patent-Class-428-289; US-Patent-Class-428-334) Avail: US Patent and Trademark Office

The invention is directed to a highly conductive lightweight hybrid material and methods of producing the same. The hybrid composite is obtained by weaving strands of a high strength carbon or graphite fiber into a fabric-like structure, depositing a layer of carbon onto the structure, heat treating the structure to graphitize the carbon layer, and intercalating the graphitic carbon layer structure. A laminate composite material useful for protection against lightning strikes comprises at least one layer of the hybrid material over at least one layer of high strength carbon or graphite fibers. The composite material of the present invention is compatible with matrix compounds, has a coefficient of thermal expansion which is the same as

underlying fiber layers, and is resistant to galvanic corrosion in addition to being highly conductive. These materials are useful in the aerospace industry, in particular as lightning strike protection for airplanes.

STRENGTHENING OF NiAl MATRIX COMPOSITES Final Report, Oct. 1990 - Sep. 1993
Richard J. Arsenault Oct. 1993 32 p
(Contract N00014-91-J-1353)
(AD-A271491; MML-1993-1) Avail: CASI HC A03/MF A01

It has finally been concluded that none of the existing theories could account for the observed high temperature strengthening, nor could the models or theories that we considered. This led to the prediction that the strengthening at high temperatures was the result of an increase in strength in the intermediate temperature range where the yield stress is relatively independent of temperature. We believe that the increase in stress is due to an increase in the athermal component of the yield stress, a component of the yield stress which is not overcome by thermal fluctuations. A TEM investigation was undertaken of continuous filament Al2O3/NiAl composites to determine if dislocations were generated as a result of the relaxation of the thermal residual stress. The data indicates that dislocation generation did indeed occur and there is a possibility that dislocation generation also occurs in shot fiber Al2O3/NiAl composites. This data may produce an interesting paradox since in Al2O3/NiAl composites, as the size of the reinforcement gets larger the dislocation density increases, but in SiC/Al composites, as the size of the SiC increases the dislocation density decreases at a constant volume fraction. INTERLEAVED BISMALEIMIDE COMPOSITES Final Report, Jul. 1989 - May 1991
Eileen Armstrong-Carroll and Thomas M. Donnellan 1 Dec. 1992 57 p
(AF Proj. RS3-4-AS-0)
(AD-A272233; NAWCADWAR-92102-60) Avail: CASI HC A04/MF A01

This report examines interleaving as a technique for the improvement of delamination resistance in composites. In particular, the influence of the deformation behavior of the interleaf film and film adhesion on composite fracture energy is studied. Teflon, E, and Kapton interleaf film materials are compared. Kapton and E films display predominantly brittle deformation behavior. Teflon exhibits substantial deformation before failure. All films are plasma treated to vary film-resin bond strengths. With the Kapton and Teflon films, plasma treatments are shown to increase film-resin adhesion and fracture energy. The effectiveness of Teflon as an interleaf material may be limited by the toughness of this film. Film-resin adhesion with the E film is determined to be optimized. Fracture energy is greatest with composites interleaved with the E film. DTIC

BIAXIAL FLEXURAL TESTING OF A CARBON FIBER REINFORCED EPOXY COMPOSITE Final Report
Nikos Tsangarakis and Barmac K. Taleghani Oct. 1993 20 p
(AD-A271956; ARL-TR-221) Avail: CASI HC A03/MF A01

The response of a 3501-6 resin composite to biaxial flexural loading was assessed using disk specimens. The composite was cross-ply reinforced with continuous carbon fibers with a volume content of 60%. Under monotonic flexural loading, the formation of delaminations limited the useful range of the composite's deformation to a biaxial tensile strain of 0.0067. Under cyclic flexural loading and for a fatigue life of 10(6) cycles, the useful strain range was limited to 0.003. The latter strain is only 19% of the composite's uniaxial tensile strain to failure. Fatigue failure mechanisms included delaminations, matrix cracking, fiber, and possible fiber bundle debonds. Some delaminations were identified with ultrasonic C-scanning. DTIC

The objective of the research was to gain fundamental knowledge of solidification microstructure evolution in the presence of constraints and to apply this knowledge to relevant intermetallic composite designs. The work involved numerical modeling, transparent material solidification and the solidification of Mg-Li and Nb-Al composites. All work was completed and several novel findings are described in this report. This report is the first comprehensive document dealing with morphological evolution of solidification microstructure when constrained by diffusional barriers with different types of interface. First time report of non-directional dendrites and S/L interface strain energies leading to defect formation are disclosed. Development strategies and microstructure maps for particulate and fiber composites are reported. DTIC

GRAPHITE/POLYURETHANE FLEXIBLE COMPOSITES: MECHANICAL AND VIBRATION DAMPING PROPERTIES
Roger M. Crane and Colin P. Ratcliffe Jul. 1993 66 p
(AD-A271608; CARDIVNSWC-TR-601-93/02) Avail: CASI HC A04/MF A01

Structures fabricated with advanced composite materials, such as graphite fibers in thermoset or thermoplastic resins, typically possess high stiffness. The material is elastic to failure, which occurs at strain levels which are relatively low, on the order of 2 to 5%, depending on fiber orientations. There are numerous naval applications in which systems are subjected to significantly large deformations due to the global deformation of the ship hull. To allow the subsystems to function while being subjected to these large global deformations, flexible couplings are often incorporated. These couplings must transfer in-plane loads and torque while allowing for dissimilar motion of each component. This paper describes such a structural configuration which is both flexible and structurally adequate to support significant mechanical loads. This flexible composite system consists of a braided graphite fiber preform infiltrated with a polyurethane, Adiprene, which has a modulus of 1100 psi and a strain to failure of 300%. This composite system possesses adequate structural characteristics of strength and stiffness, the capability to undergo large global deformations, while simultaneously dissipating significant levels of mechanical vibration energy. This paper discusses the fabrication and design of the flexible composite material, the mechanical characteristics and the damping that it provides.

FIBER REINFORCED THERMOSETTING RESIN COMPOSITION WITH COATED FIBERS FOR IMPROVED TOUGHNESS Patent
Arutun Maranci, inventor (to American Cyanamid Co.) 11 Aug. 1992 37 p Filed 21 Dec. 1987
(CA-Patent-1,306,320; Int-Patent-Class-C08J-5/06; Int-Patent-Class-C08G-59/50; CTN-93-60688) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

Thermosettable resins are known to be useful in conjunction with fibrous reinforcing materials to form composite articles characterized by high strength to weight ratios for use in aircraft and aerospace industries, as well as in other commercial applications. A fiber-resin matrix composition is disclosed, comprised of reinforcing fibers precoated with a fiber- and matrix resin-reactive elastomeric material, forming a covalently bonded bridging layer between the fibers and the matrix resin, and a heat-curable resin composition comprising an epoxy prepolymer or combination of epoxy prepolymers having more than one epoxide group per molecule and an effective amount of an amine curing agent. The use of an elastomeric coating on the fiber surface in accordance with this invention results in improvements in the fracture resistance, in comparison with compositions and composite articles in which the fibers are not so coated. Moreover, this is accomplished while maintaining the hot-wet properties. Other facets of the invention comprise composite articles formed from the above mentioned compositions, structural members prepared from the composites, and processes for applying reactive elastomeric coatings to fibers, fiber tapes, fabrics, and rovings. Experiments are described to illustrate aspects of the invention. Author (CISTI)

This is a study of the application of induction heating to graphite-based composites, both thermoset and thermoplastic. Panels of IM-6/3501-6 and IM-6/PEEK were processed in magnetic fields of 450-kHz and 25-kHz frequencies. A 15.24-cm-diameter pancake-type induction coil was used with 10.2-cm x 10.2-cm, 16-ply specimens. Vacuum bagging provided the only consolidation pressure. Data include resin, fiber, void contents, 3-pt. and 4-pt. loading for mechanical properties evaluation, and thermal analysis (DSC and TMA). Comparisons are made to similar samples processed under a standard autoclave cycle. Additional variables studied and discussed include the use of various caul plate materials as field susceptors, effects of coil vibration, various prepreg lay-up orientations, and other sample thicknesses. A brief discussion of the overall field effects and value of induction heating for field repair is included. DTIC

PROPERTIES OF E-BEAM INTERACTIVE OXIDE FILMS FOR NANOMETER SCALE STRUCTURES Final Report, 1 Oct. 1988 - 1 Dec. 1993
R. C. Buchanan, J. L. Hollenbeck, and J. Kim 5 Nov. 1993 40 p
(Contracts N00014-88-K-0317; N00014-92-J-1868)
(AD-A272848) Avail: CASI HC A03/MF A01

E-beam generated ultrastructures on oxide film substrates have been investigated for high density memory and lithographic applications. In order to create the nanometer scale patterns (holes, lines, channels), a dedicated STEM has been used; it was also used for exposure studies, imaging, microdiffraction analysis, and monitoring the transmitted beam studies. Amorphous films of Al2O3, Y2O3, Sc2O3, 3Al2O3-2SiO2, and MgO-Al2O3 are deposited on to substrate at cryogenic temperature. Amorphous film structure is necessary to achieve rapid removal of material during e-beam exposure. Hole resolution in the sputtered oxide films of 5 nm holes on 8.1 nm centers was achieved with exposure times in the millisecond range, two to three orders of magnitude lower than produced by other technique. Deposition parameters and film thickness have been studied. The gas ambient on thin films electron dose are strongly related to the drilling speed. A possible mechanism for the exposure process is also developed. DTIC

A STUDY OF THE STRUCTURAL STABILITY OF AN UNBALANCED SANDWICH COMPOSITE CONFIGURATION M.S. Thesis
Mary C. Murphy Jun. 1993 60 p
(AD-A272496) Avail: CASI HC A04/MF A01

An unbalanced, sandwich composite structure consisting of Ti 6AL-4V and GRP (Glass Reinforced Plastic) skins with a phenolic honeycomb core is being considered for construction of a surface ship mast which will enclose critical shipboard equipment. Stability of the structure is one of the major concerns in the design process. This research focuses on analytical and experimental studies of an unbalanced composite sandwich beam subject to a compressive axial load. The limit load of each skin material separately, and two failure modes of the sandwich construction (general buckling and core shearing) are measured in the laboratory. An analytical model is developed for predicting the limit load of the unbalanced, sandwich composite configuration. DTIC

Sponsored by NASA. Washington
(RTOP 510-01-50)
(NASA-TM-106285; E-8023; NAS 1.15:106285) Avail: CASI HC A03/MF A01

A study was conducted to investigate the relationship between the thermo-oxidative stability of PMR-15 matrix resin and the stability of graphite-fiber-reinforced composites that contain this resin as the matrix material. Three areas were investigated. The first was the effect of fiber/matrix interfacial bond strength on the isothermal aging weight loss of composites. By using type-A graphite fibers produced by Hercules, it was possible to study composites reinforced with fibers that were processed to receive different surface treatments. One of the fibers was untreated, a second fiber was treated by oxidation to enhance fiber/matrix bonding, and the third type of fiber was coated with an epoxy sizing. These treatments produced three significantly different interfacial bond strengths. The epoxy sizing on the third fiber was quickly oxidized from the bare fiber surfaces at 288, 316, and 343 C. The weight loss due to the removal of the sizing was constant at 1.5 percent. This initial weight loss was not observed in thermo-oxidative stability studies of composites. The PMR-15 matrix satisfactorily protected the reinforcemnt at all three temperatures. Author (revised)

DAMAGE STATES AROUND FASTENER HOLES IN THICK GRAPHITE/EPOXY COMPOSITE LAMINATES
S. C. Galea, G. K. Deirmendjian, and D. S. Saunders Aug. 1993 46 p
Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272613; ARL-RR-12; DODA-AR-006-673) Avail: CASI HC A03

This report presents qualitative studies of the development of damage around countersunk fastener holes in thick graphite/epoxy laminates which have been subjected to fatigue loading. The experiments have shown that damage at the hole bore surface produces sites for the nucleation of delaminations. The morphology of the delaminations and ply cracking was mapped extensively. This report discusses the methods used for the mapping of the damage and presents detailed maps of the damage for two loading conditions. In addition, several methods for the nondestructive monitoring of damage development and growth were investigated. These were load/displacement hysteresis measurements, fastener tilt measurements using shadow moire fringe techniques, and ultrasonic time-of-flight C-scanning. This report briefly discusses the possible mechanisms by which damage develops and grows around fastener holes. From the damage maps it was found that the volume of material around the fastener hole, damaged by the fatigue loading, adopted a characteristic shape; the volume of damaged laminate increased towards the faying surface of the laminate and metal fixture. This characteristic damage volume was generated by the fastener rocking under the fatigue loads. The growth of the delaminations has been shown to be preceded by intra-ply cracking and, as fatigue loading continued, more delaminations were generated at the hole bore surface. Author (revised)

DEFORMATION OF AN ALUMINA-ZIRCONIA-SILICON CARBIDE-WHISKER REINFORCED COMPOSITE
J. M. Calderon-Moreno, A. R. DeArellano-Lopez, A. Dominguez-Rodriguez, J. L. Routbort (Argonne National Lab., IL.), and T. Leasky (MER Corp., Tucson, AZ.) Apr. 1993 7 p Presented at the 3rd Conference of the European Ceramic Society, Madrid, Spain, 13-17 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-040244; ANL/MSD/CP-79645; CONF-930927-2) Avail: CASI HC A02/MF A01

Alumina-zirconia composites (MERC) with the addition of 0 and 28 vol % of silicon carbide whiskers were deformed under compression at constant rate at 1450 C, in air. Mechanical results are compared with the behavior of a commercial alumina (ARCO) with analogous proportions of silicon carbide-whiskers (0 and 30 vol %), under the same testing conditions. Flow stresses are typically higher for ARCO materials than for MERC materials. The addition of SiC whiskers increases flow stresses in ARCO composites, and decreases them for MERC samples. Microstructural observations confirm that the change in flow stress is the result of the presence of a glass phase in the MERC samples. DOE

MODELING OF OUTGASSING AND MATRIX DECOMPOSITION IN CARBON-PHENOLIC COMPOSITES Semiannual Progress Report, Jun. - Dec. 1993
Hugh L. McManus Dec. 1993 10 p
(Grant NAG8-295)
(NASA-CR-194741; NAS 1.26:194741) Avail: CASI HC A02/MF A01

A new release rate equation to model the phase change of water to steam in composite materials was derived from the theory of molecular diffusion and equilibrium moisture concentration. The new model is dependent on internal pressure, the microstructure of the voids and channels in the composite materials, and the diffusion properties of the matrix material. Hence, it is more fundamental and accurate than the empirical Arrhenius rate equation currently in use. The model was mathematically formalized and integrated into the thermostructural analysis code CHAR. Parametric studies on variation of several parameters have been done. Comparisons to Arrhenius and straight-line models show that the new model produces physically realistic results under all conditions. Derived from text

BEST-CMS (boundary element solution technology - composite modeling system) is an advanced engineering system for the micro-analysis of fiber composite structures. BEST-CMS is based upon the boundary element program BEST3D which was developed for NASA by Pratt and Whitney Aircraft and the State University of New York at Buffalo under contract NAS3-23697. BEST-CMS presently has the capabilities for elastostatic analysis, steady-state and transient heat transfer analysis, steady-state and transient concurrent thermoelastic analysis, and elastoplastic and creep analysis. The fibers are assumed to be perfectly bonded to the composite matrix, or in the case of static or steady-state analysis, the fibers may be assumed to have spring connections, thermal resistance, and/or frictional sliding between the fibers and the composite matrix. The primary objective of this user's manual is to provide an overview of all BEST-CMS capabilities, along with detailed descriptions of the input data requirements. In the next chapter, a brief review of the theoretical background is presented for each analysis category. Then, chapter three discusses the key aspects of the numerical implementation, while chapter four provides a tutorial for the beginning BEST-CMS user. The heart of the manual, however, is in chapter five, where a complete description of all data input items is provided. Within this chapter, the individual entries are grouped on a functional basis for a more coherent presentation. Chapter six includes sample problems and should be of considerable assistance to the novice. Chapter seven includes capsules of a number of fiber-composite analysis problems that have been solved using BEST-CMS. This chapter is primarily descriptive in nature and is intended merely to illustrate the level of analysis that is possible within the present BEST-CMS system. Chapter eight contains a detail description of the BEST-CMS Neutral File which is helpful in writing an interface between BEST-CMS and any graphic post-processor program. Finally, all pertinent references are listed in chapter nine.

COMPILATION OF REINFORCED CARBON-CARBON TRANSATLANTIC ABORT LANDING ARC JET TEST RESULTS Study/Test Results, Dec. 1987 - Mar. 1992
James D. Milhoan, Vuong T. Pham, and Eric H. Yuen Dec. 1993 334 p
(NASA-TM-104778; S-735; NAS 1.15:104778) Avail: CASI HC A15/MF A03

This document consists of the entire test database generated to support the Reinforced Carbon-Carbon Transatlantic Abort Landing Study. RCC components used for orbiter nose cap and wing leading edge thermal protection were originally designed to have a multi-mission entry capability of 2800 F. Increased orbiter range capability required a predicted increase in excess of 3300 F. Three test series were conducted. Test series #1 used ENKA-based RCC specimens coated with silicon carbide, treated with tetraethyl orthosilicate, sealed with Type A surface enhancement, and tested at 3000-3400 F with surface pressure of 60-101 psf. Series #2 used ENKA- or AVTEX-based RCC, with and without silicon carbide, Type A or double Type AA surface enhancement, all impregnated with TEOS, and at temperatures from 1440-3350 F with pressures from 100-350 psf. Series #3 tested ENKA-based RCC, with and without silicon carbide coating. No specimens were treated with TEOS or sealed with Type A. Surface temperatures ranged from 2690-3440 F and pressures ranged from 313-400 psf. These combined test results provided the database for establishing RCC material single-mission-limit temperature and developing surface recession correlations used to predict mass loss for abort conditions.

This tenth compilation of outgassing data of materials intended for spacecraft use supersedes Reference Publication 1124, Revision 2, November 1990. The data were obtained at the Goddard Space Flight Center (GSFC), utilizing equipment developed at Stanford Research Institute (SRI) under contract to the Jet Propulsion Laboratory (JPL). SRI personnel developed an apparatus for determining the mass loss in vacuum and for collecting the outgassed products. The outgassing data have been presented in three different ways in order to facilitate material selection. In Section A, the materials are divided by category into the 18 probable uses, such as adhesives, greases, paints, potting compounds, and so forth. In Section

B, all the materials contained in Section A are listed in alphabetical order by the manufacturer's identification. In Section C, the only materials listed are those having 'Total Mass Loss' (TML) and Collected Volatile Condensable Materials (CVCM) equal to or lower than a maximum 1.0 percent TML and a maximum 0.10 percent CVCM. These are grouped by use, as in Section A. Derived from text

This work addresses the application and evaluates the potential of mm-wave imaging in the W-band (75-110 GHz) using samples of low-loss dielectric and composite materials with artificial defects. The initial focus is on the measurement of amplitude changes in the back scattered and forward-scattered fields. The c-scan system employs a focused beam antenna to provide spatial resolution of about one wavelength. A plane-wave model is used to calculate the effective reflection (or transmission) coefficient of multilayer test sample geometry. Theoretical analysis is used to optimize the measurement frequency for higher image contrast and to interpret the experimental results. Both reflection and transmission images, based on back scattered and forward-scattered powers, were made with Plexiglas and Kevlar/epoxy samples containing artificially introduced defects such as subsurface voids and disbonds. The results clearly indicate that mm-wave imaging has high potential for non-contact interrogation of low-loss materials. DOE

FABRICATION OF WHISKER-TOUGHENED ALUMINA TUBES
Raouf O. Loutfy Sep. 1993 58 p Prepared in cooperation with Oak Ridge National Lab., TN
(Contract DE-AC05-84OR-21400)
(DE94-001012; ORNL/Sub-86-SE793C) Avail: CASI HC A04/MF A01

A process has been developed to fabricate whisker toughened alumina composites by slip casting dense colloidal suspensions of Al2O3-15% SiC(w). Optimum processing parameters for slip casting were developed with slip viscosity of 60-70 centipoise and solids content 78-79 wt %. Slip-cast parts with green densities 65 to 68% theoretical were achieved. Composite parts were pressureless sintered to 96-97% theoretical density with less than 1% open porosity. The composites exhibited strengths of 500 MPa, toughness of 6.5 MPa m(exp 1/2), and hardness of 17.26 GPa (1765 kg/mm(exp 2)). High temperature strength retention was maintained up to 1200 C. Good thermal shock resistance with (Delta)T(sub cr) = 500 C was also achieved. The process technology was transferred into pilot scale for producing prototype heat exchanger tubing up to 4 inches in diameter at the facilities of Vesuvius/McDanel. DOE

CREEP DAMAGE OF CARBON FIBER REINFORCED PEEK M.S. Thesis [ENDOMMAGEMENT EN FLUAGE DU PEEK RENFORCE PAR DES FIBRES DE CARBONE]
Hamid OuldBrahim Jun. 1990 149 p In FRENCH
(ISBN-0-315-58962-0; CTN-94-60887) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The evolution of viscoelastic properties of a polyether ether ketone (PEEK)/carbon composite under creep loading in the transverse direction was investigated at various temperatures. Using the concept of effective stress, damage development was monitored through the measure of stiffness loss. Creep rupture is also discussed. Creep tests at four normalized stress levels were conducted on specimens of APC-2 until rupture occurred. Four temperatures in the glass transition zone were studied. After different periods of creep, static tests were performed and stiffness recorded. Results showed nonlinear creep behavior and an absence of the tertiary stage of creep. The strain at which the nonlinearity occurred decreased with increasing temperature. The creep behavior can be described by a power law function with an independent temperature exponent. The possibility of interpolation at intermediate temperatures was demonstrated. Damage progression was found to be linear and damage was linked to the nonlinear creep behavior. The stress and temperature was shown to influence damage. A temperature of 120 C appeared critical for the matrix-fiber interface. Kachanov's damage theory gave a good prediction of the time to failure, while the universality of Zhurkov's model was not confirmed. Author (CISTI)

THE EFFECT OF DELAMINATION ON THE DYNAMIC RESPONSE OF COMPOSITE LAMINATES AS MEASURED BY EMBEDDED FIBER OPTIC MICHELSON SENSOR M.S. Thesis
Gao Peiliang 1993 139 p
(ISBN-0-315-83534-6; CTN-94-60949) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Inferring damage to composite materials from their acoustic emissions may pose some limitations to practical uses. The vibration method may be an alternative technique for detecting damage in composites. Delamination alters the dynamic behavior of structures made of composite materials. The effects of delaminations of various sizes in various locations on the dynamic response of a composite laminated beam structure was investigated experimentally. An embedded localized fiber optic Michelson sensor was employed to detect the dynamic response of the test specimen. The influence of embedded fiber sensors on the natural frequencies of the test specimens was also examined. Extensive experimental results are reported. Neither inside nor edge delamination was shown to affect the natural frequencies of the test sample, but through-width delamination and full edge delamination did affect the damping capacities of the samples. The analytical results based on the beam theory model are presented, which show good agreement with the experimental results. Author (CISTI)

AN EMBEDDED FIBRE OPTIC FOR DAMAGE GROWTH MONITORING IN KEVLAR COMPOSITES M.S. Thesis
William Tsaw 1992 159 p
(ISBN-0-315-83501-X; CTN-94-60951) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The growth of damage in Kevlar composites was studied using embedded optical fibers in the specimens. It was found that the embedded optical fibers were able to detect and monitor damage growth from simple, one delamination interface layups to complex layups in the DeHavilland Dash-8 leading edge. Furthermore, the results reinforced the damage mechanics as suggested by Glossop (1988). In addition, the data also revealed that the damage mechanisms in the laminates were similar to those proposed by the K-Rule (Gosse et al, 1987, 1988) which describes the relationship between transverse cracks and delaminations. The use of image enhanced backlighting provided a useful nondestructive technique to verify the accuracy of the fracture of the optical fibers. The results also provided clues to the damage progression of thin plates subjected to low-velocity impacts.

COYOTE and similar combustion programs based on the multicomponent Navier-Stokes equations require the mixture viscosity, thermal conductivity, and species transport coefficients as input. This report documents a significant improvement to the calculation of these molecular transport coefficients in COYOTE and provides a self-contained and easy-to-use source of such data in a format suitable for use by such programs. The paper presents the data for various species in two forms. The first is a simple functional fit to the transport coefficients. The second is the use of tabulated Lennard-Jones parameters in simple theoretical expressions for the gas-phase transport coefficients. Tables are given for a number of chemical species. DOE

The design of the quench reactor was completed. A high temperature furnace, capable of reaching 1540 C was ordered. Thermodynamic equilibrium calculations were carried out in order to determine the maximum possible yields of various products from methane pyrolysis, assuming that the reaction could be quenched at C10 aromatics. Acetylene, benzene, and naphthalene were identified as the major products of such a process. Ethylene, propylene, cyclopentadiene, methylnaphthalene and toluene, vinylacetylene, butadiene, and propadiene were identified as minor products. The yields of benzene and naphthalene are highest in the temperature range between 1350-1550 K, with a maximum aromatic yield of ca. 45% (benzene + naphthalene) expected at about 1475 K (ca. 1200 C). (AD-A270705; AFIT/GAP/ENP/93S-01) Avail: CASI HC A04

Zinc germanium diphosphide (ZnGeP2) is a chalcopyrite semiconductor with strong nonlinear optical properties and potential application in Air Force interests. The characteristics of this material have been studied using photoluminescence (PL) spectroscopy. The PL spectrum is dominated by transitions from the conduction band to a deep acceptor level, and features in the spectrum suggest that more than one transition is being observed. The PL is partially polarized, and the degree of polarization appears to differ for each feature in the spectrum. The relative PL intensity of these features are seen to depend upon the wavelength of the excitation source in a fashion which suggests that the observed transitions may originate from three separate conduction bands. These experimentally observed results are found to agree qualitatively with the published band structure of ZnGeP2. DTIC

Analytical and experimental studies for the morphology and dynamics of agglomerated particulates in combustion systems were carried out. The analytical studies entailed the investigation of the validity of the approximate relations for scattering and absorption characteristics as well as predictions of the depolarized light scattering intensities for the agglomerates as functions of primary particle diameter, primary particle number density, scattering angle and optical properties of the particles. The approximate relations were found to be accurate to within 20% or better for agglomerates consisting of Rayleigh size primary particles and with optical properties typical of flame soot. It was found that the agglomerate structures encountered in typical flame systems and other agglomerates composed of metallic or dielectric spheres the reciprocity relations do not hold. Experiments were carried out utilizing latex spheres dispersions in distilled water. The results indicate that multiple scattering within the agglomerate may be the cause for the significant difference (up to 30% or more) of the depolarization ratio from the expected value of 1.0. CATALYTIC HYDROGENATION OF CARBON MONOXIDE

B. B. Wayland Dec. 1993 8 p
(Contract DE-FG02-86ER-13615)
(DE94-000881; DOE/ER-13615/7) Avail: CASI HC A02/MF A01

Focus of this project is on developing new approaches for hydrogenation of carbon monoxide to produce organic oxygenates at mild conditions. The strategies to accomplish CO reduction are based on favorable thermodynamics manifested by rhodium macrocycles for producing a series of intermediates implicated in the catalytic hydrogenation of CO. Metalloformyl complexes from reactions of H2 and CO, and CO reductive coupling to form metallo alpha-diketone species provide alternate routes to organic oxygenates that utilize these species as intermediates. Thermodynamic and kinetic-mechanistic studies are used in guiding the design of new metallospecies to improve the thermodynamic and kinetic factors for individual steps in the overall process. Electronic and steric effects associated with the ligand arrays along with the influences of the reaction medium provide the chemical tools for tuning these factors. Non-macrocyclic ligand complexes that emulate the favorable thermodynamic features associated with rhodium macrocycles, but that also manifest improved reaction kinetics are promising candidates for future development. DETAILED STRUCTURE STUDY OF AN H2/N2O/Ar FLAME EMPLOYING MOLECULAR BEAM MASS SPECTROMETRY, LASER SPECTROSCOPY, AND MODELING Final Report, Jun. 1992 - Jan. 1993
Rosario C. Sausa, David C. Dayton, William R. Anderson, Cynthia M. Faust, and Stephen L. Howard Oct. 1993 56 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-61102-AH-43)
(AD-A270720; ARL-TR-232) Avail: CASI HC A04

A combined experimental and detailed chemical modeling study has been performed on a 20-torr, stoichiometric H2/N2O/Ar burner stabilized flame. This study provides a check of part of the mechanism to be used in models for the combustion of solid nitramine propellants. Species concentration profiles were measured using molecular beam sampling with mass spectrometric detection and laser-induced fluorescence, while temperature profiles were measured with coated Pt/Pt-Rh(10%) thermocouples. The burned gases of the flame contain about 2 mole % of NO and H2, a concentration of approximately 10 times more than that of their equilibrium. This formation prevents full energy release of the systems within or near the flame zone. Experimental flame profiles of the major species, H2, N2O, N2, and H2O, as well as the minor species, NO, O2, OH, H, O, and NH, are presented and compared to calculated profiles generated by PREMIX, a one-dimensional premixed laminar flame code. The chemical mechanism used in the flame code was derived from a critical literature review and consists of 38 reactions and 14 species. Rate and sensitivity analyses performed reveal the intricacies of the mechanism as well as reactions important in the modeling of the experimental results. Several key reactions, including N2O + OH = HO2 + N2 = NO + NH, whose rate coefficients have been controversial, are discussed in detail. In addition, the importance of various collision partners in the key initiation step, N2O + M = N2 + O + M, is presented and discussed. DTIC

COMPUTED POTENTIAL ENERGY SURFACES FOR CHEMICAL REACTIONS Periodic Research Report, 1 Jan. - 31 Aug. 1993
Stephen P. Walch and Eugene Levin 12 Oct. 1993 119 p
(Contract NCC2-478)
(NASA-CR-194600; NAS 1.26:194600) Avail: CASI HC A06/MF A02

A new global potential energy surface (PES) is being generated for O(P-3) + H2 yields OH + H. This surface is being fit using the rotated Morse oscillator method, which was used to fit the previous POL-CI surface. The new surface is expected to be more accurate and also includes a much more complete sampling of bent geometries. A new study has been undertaken of the reaction N + O2 yields NO + O. The new studies have focused on the region of the surface near a possible minimum corresponding to the peroxy form of NOO. A large portion of the PES for this second reaction has been mapped out. Since state to state cross sections for the reaction are important in the chemistry of high temperature air, these studies will probably be extended to permit generation of a new global potential for reaction. HYDROGEN ISOTOPE SEPARATION EXPERIENCE AT THE SAVANNAH RIVER SITE
M. W. Lee 1993 5 p Presented at the Course and Workshop on Tritium Technology for Fusion Reactors, Varenna, Italy, 6-14 Sep. 1993
(Contract DE-AC09-89SR-18035)
(DE93-019832; WSRC-MS-93-255; CONF-930937-2) Avail: CASI HC A01/MF A01

Savannah River Site (SRS) is a sole producer of tritium for U.S. weapons program. SRS has built facilities, developed the tritium handling processes, and operated safely for the last forty years. Tritium is extracted from the irradiated reactor target, purified, mixed with deuterium, and loaded to the booster gas bottle in the weapon system for limited lifetime. Tritium is recovered from the retired bottle and recycled. Newly produced tritium is branded into the recycled tritium. One of the key processes is the hydrogen isotope separation that tritium is separated from deuterium and protium. Several processes have been used for the hydrogen isotope separation at SRS: thermal diffusion column (TD), batch cryogenic still (CS), and batch chromatography called fractional sorption (FS). TD and CS requires straight vertical columns. The overall system separation factor depends on the length of the column. These are three story building high and difficult to put in glove box. FS is a batch process and slow operation. An improved continuous chromatographic process called thermal cycling absorption process (TCAP) has been developed. It is small enough to be able to put in a glove box yet high capacity comparable to CS. The SRS tritium purification processes can be directly applicable to the fusion fuel cycle system of the fusion reactor. DOE

CHARACTERIZATION OF AMORPHOUS MATERIAL IN SHOCKED QUARTZ BY NMR SPECTROSCOPY
R. A. Assink, M. B. Boslough, and R. T. Cygan 1993 10 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019069; SAND-93-0441C; CONF-930676-34) Avail: CASI HC A02/MF A01

Nuclear magnetic resonance (NMR) analysis of the recovered products from a series of controlled explosive shock-loading experiments on quartz powders was performed to investigate shock-induced amorphization processes. Silicon-29 NMR spectroscopy is an excellent probe of the local bonding environment of silicon in minerals and is capable of detecting and characterizing amorphous and disordered components. NMR spectra obtained for the recovered material exhibit a narrow resonance associated with the shocked crystalline material, and a broad component consistent with an amorphous phase despite the absence of evidence for glass from optical microscopy. The NMR measurements were performed over a range of recycle times from 1 to 3 x 10(exp 5) S. Results demonstrate that the magnetization in both the crystalline and amorphous material following power-law behavior as a function of recycle time. The amorphous component dominates the spectra for short NMR recycle times due to its shorter relaxation time relative to the crystalline material. Fractal analysis of the power-law relations suggests a fractal dimension of 2 for the amorphous phase and 3 for the crystalline phase. DOE

STABILITY OF THE FACE-CENTERED-CUBIC PHASE OF HEAVY RARE GAS SOLIDS
F. H. Ree and Yumi Choi (Korea Advanced Inst. of Science and Technology, Taejon, Republic of Korea.) Jul. 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-019949; UCRL-JC-113296; CONF-930676-42) Avail: Issuing Activity (Department of Energy (DOE))

The authors' recent perturbation theory is applied to show that heavy rare gases solidify into a face-centered-cubic phase over a large temperature range near the melting lines. This paper investigates the static, harmonic,

and anharmonic contributions to the excess Helmholtz free energy and the stability to the face-centered-cubic phase. The observed stability is due to thermal contributions in the Helmholtz free energy. DOE

IN-SITU ELECTROCHEMICAL SURFACE SCIENCE
Michael J. Weaver and Xiao-Ping Gao Apr. 1993 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1409)
(AD-A265942; TR-137) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We consider here recent experimental findings taken primarily from three types of microscopic-level techniques which can yield direct structural information for both in-situ electrochemical and uhv-based surfaces. The first type, scanning probe microscopies, and in particular scanning tunneling microscopy (STM), has recently been shown to reveal remarkably detailed information on real-space atomic arrangements as well as larger-scale morphologies on ordered metal surfaces in solution as well as in uhv and gas-phase environments. The second class, x-ray synchrotron-based scattering techniques, provides accurate spatial structural information. Together, these methods are beginning to revolutionalize our appreciation of surface crystallography at in-situ electrochemical interfaces. The third category considered here, albeit more cursorily, is surface vibrational spectroscopy, specifically infrared reflection-absorption (IRAS) and surface-enhanced Raman (SERS) spectroscopies. While quite different in character and applicability, both these vibrational techniques can yield important insight into the chemical nature and bonding properties of electrochemical adsorbates, and the influences exerted by the local electrostatic and chemical environment. Smoke was generated from zinc/hexachloroethane and titanium dioxide/hexachloroethane pyrotechnical pictures in a closed space. The following parameters were investigated: smoke concentration, particle size distributions and chemical composition of the smoke. Zinc hydroxy acids, which are strong acids, are formed during combustion of the zinc munition. The titanium tetrachloride formed in smoke from the titanium dioxide munition will rapidly hydrolyze to hydrogen chrloride and titanium dioxide. Several chlorinated organic substances are formed from both types of smoke munitions during combustion. Some of these substances have well documented toxic and mutagenic effects, for example hexachlorobenzene, hexachlorobutadiene and chlorinated dibenzofurans and dibenzodioxins. The amount of byproducts formed is higher from the titanium dioxide/hexachloroethane munition than from the zinc munition. ESA

APPLICATION OF THE REACTIVE FLUX FORMALISM TO STUDY WATER HYDROGEN BOND DYNAMICS Interim Report, Apr. 1992 - Oct. 1993
A. Luzar and D. Chandler Oct. 1993 2 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1361)
(AD-A271824; TR-3) Avail: CASI HC A01

We performed a molecular dynamics study of water at room temperature to examine the dynamics of hydrogen bond formation. It was carried out through an application of the reactive flux formalism. Computed long time relaxation functions are not consistent with a first-order process. Statistical (nondynamical) theories of hydrogen bond breaking, such as transition state theory with a single dividing surface, are found to be unsatisfactory. Further, our dynamical results indicate that at least two elementary processes contribute to hydrogen bond breaking. DTIC

DIAGNOSTICS AND METHODS FOR REAL-TIME LASER MICROCHEMISTRY Final Report, 1 Apr. 1992 - 31 Mar. 1993
Daniel Ehrlich 31 Mar. 1993 7 p
(Contract F49620-92-C-0029)
(AD-A270871; AFOSR-93-0778TR) Avail: CASI HC A02/MF A01

Among the main goals of the program was the development of digital real-time microchemical processes and diagnostics. Further objective was the design of a stable platform, and the mechanical subsystems and electronic circuits to provide real-time machine control. These are the basis for the study of control and stabilization methods. Specific subassemblies designed were the massive 1.5-inch-thick steel plate, the mechanical frame support, the vibration isolators, and the sliding cell supports. In addition design of the main control circuits, including those for laser incident-light feed-back, laser reflected light, illumination control, opto-interrupt for vibration isolation and zoom magnification control, were completed. Our goal is to carry out ultra-precise laser spectroscopy on trapped atomic hydrogen in the microkelvin regime, and to develop methods for measuring the 1S-2S transition frequency. The major effort during this past year was to perfect methods for carrying out ultraviolet laser spectroscopy in our cold hydrogen trap. We carried out extensive investigations on the absorption of UV light in various window materials, achieving values of a few percent. In addition, we developed a new method for dealing with the heat deposited in the window by controlling the helium film that lines the low temperature cell in which the experiment is performed. Other accomplishments include the development of improved instrumentation for spatially stabilizing and amplitude modulating the 243 nm laser beam, and improvements in the frequency control of the laser system. (DE93-041232; DOE/PC-92529/T3) Avail: CASI HC A02/MF A01

This report summarizes studies on the partial oxidation of methane on Li promoted vanadium phosphate, unsupported and supported on silica. Our previous report summarized the results on the unpromoted form of the same catalysts. However, we found that for the same level of conversion, Li promotion increased the formaldehyde selectivity in both the unsupported and silica supported forms. So we conducted further studies to determine the role of Li and the mechanism of promotion on these catalysts. DOE

DIRECT IMAGES OF THERMAL DISORDER IN THE Cl-Si AND H-O-Si CHEMISORPTION BOND ON Si(100) Technical Report
Q. Gao, Z. Dohnalek, C. C. Cheng, W. J. Choyke, and J. T. Yates, Jr. 27 Oct. 1993 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-82-0280)
(AD-A272386; TR-59) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The electron stimulated desorption ion angular distribution (ESDIAD) technique combined with a digital subtraction method have been employed to generate difference ESDIAD patterns between measurements made at 130K and 305K for both adsorbed Cl and OH on Si(100). The difference ESDIAD patterns reveal, in real space, images of the thermally excited vibrational amplitudes of the adsorbates. This permits a qualitative visualization of the potential energy surface associated with an adsorbate on its adsorption site. For Cl/Si(100), isotropic thermal broadening of the Cl(+) beams from 130K to 305K is observed. In contrast OH/Si(100) exhibits anisotropic thermal broadening of the H(+) beams on heating from 130K to 305K. These results are correlated with the vibrational frequencies of the surface oscillators. DTIC

A PROPOSED METHODOLOGY FOR COMBUSTION TOXICOLOGY TESTING OF COMBINED HALON REPLACEMENT AGENT/JET FUEL INTERACTION Final Report, Jun. - Sep. 1991
Charles J. Kibert Apr. 1993 67 p
(AF Proj. 6302)
(AD-A272695; AL/OET-TR-1993-0047) Avail: CASI HC A04/MF A01

An international consensus to remove chlorofluorocarbon (CFC) compounds from production and U.S. national policy to implement the resulting protocols has motivated the U.S. Air Force to embark on a program to find a suitable replacement for Halon 1211, currently used to extinguish flight line fires. This research addressed the feasibility of conducting a combustion toxicology (CT) program to assess the toxic products of the combustion interaction of JP-8 and the Group 1 or so-called Near Term candidate replacement agents for Halon 1211: HCFC's -123, -124, and -142b. A laboratory scale experiment benchmarked on large scale testing of a 150 sq ft pool fire was developed on the basis of Froude scaling of the full scale fire to a 15 x 15 cm pan fire. A prototype apparatus was developed and investigation into the use of animal behavior methods as an indicator of human incapacitation was conducted. The result is a new method which may potentially be utilized for future toxicity studies of the combustion interaction of current and future U.S. Air Force fuels with various fire extinguishants. ELECTROCHEMICAL SYNTHESIS OF ULTRATHIN FILM COMPOSITE MEMBRANES Final Technical Report, 1 Jun. 1990 - 31 May 1993
C. R. Martin 27 Oct. 1993 23 p
(Grant AF-AFOSR-0282-90)
(AD-A272721; Rept-53-2380; AFOSR-93-0845TR) Avail: CASI HC A03/MF A01

Ultrathin film composite membranes consist of an ultrathin (less than 1,000 A-thickness) chemically-selective layer bonded to the surface of a microporous support membrane. Such composite membranes are important in electrochemical science because they can provide both high transport selectivity and low membrane resistance. This is possible because, while the chemically selective layer typically has high resistivity, its ultrathin nature insures that it has low resistance. We have been exploring new methods for synthesizing ultrathin film composite membranes, and we have been investigating the transport properties of the resulting composite membranes. This research effort has been extremely successful. DTIC

CHEMISTRY OF THE BURNING SURFACE Final Report, 1 Oct. 1989 - 30 Sep. 1993
Thomas B. Brill 12 Oct. 1993 202 p
(Grant AF-AFOSR-0521-89)
(AD-A272725; AFOSR-93-0840TR) Avail: CASI HC A10/MF A03

The objective of this project was to identify the dominant thermal decomposition and secondary reaction pathways that exist in the surface zone of a burning propellant. T-jump/FTIR spectroscopy and SMATCH/FTIR spectroscopy are new diagnostic techniques that were designed for this project. They enable a film of material to be heated at a high rate in such a manner as to simulate a thin volume element of the surface during combustion. The semiglobal thermal decomposition reactions and the first strongly exothermic secondary reaction of important oxidizers and monopropellants were identified. The compounds studied were nitramine (CL-20, HMX, RDX, DNNC), ammonium salts (AP, AN, ADN), and azide polymers (GAP, BAMO). DTIC

REACTION ZONE MODELS FOR VORTEX SIMULATION OF TURBULENT COMBUSTION Annual Technical Progress Report, 1 Sep. 1992 - 31 Aug. 1993
Ahmed F. Ghoniem 1 Oct. 1993 113 p
(Contract F49620-92-J-0445)
(AD-A272723; AFOSR-93-0835TR) Avail: CASI HC A06/MF A02

During the first year of this effort, two related issues were investigated: (1) establishing the validity of the thin flame model when used to compute flow-combustion interactions in a turbulent shear layer; and (2) developing an efficient methodology to compute the unsteady strained flame structure when the flame thickness is much smaller than the flow scale. In the first effort, the transport element method was applied to compute (1) a reacting flow in which combustion proceeds according to a single-step, temperature dependent Arrhenius reaction, and (2) a mixing-limited model in which Schvab-Zeldovich variables are used to obtain the infinite speed chemistry results. The results of both computations showed that, at high Damkohler numbers, while there is a small error in the prediction of the total burning rate using the second approach, the second model accurately estimates the effect of combustion on the flow dynamics in terms of volumetric expansion and vorticity generation. Work on the second project resulted in a more efficient model to compute the flame structure under conditions of unsteady strain. The computational model is based on a series of mathematical transformations which reduce the governing equations to time-dependent reaction-diffusion equations. DTIC

CONVERSION OF LDEF EXPERIMENT M0003 SAMPLE OBSERVATION DATABASE TO MS-DOS FORMATS
B. C. Trotter, J. M. Coggi, and S. R. Gyetvay 1 Oct. 1993 51 p
(Contract F04701-88-C-0089)
(AD-A272945; TR-93(3935)-16; SMC-TR-93-55) Avail: CASI HC A04/MF A01

The four trays of the M0003 materials on the Long Duration Exposure Facility (LDEF) contained over 1200 samples from 20 subexperiments. The complete sample complement represented a broad range of materials, including thin-film optical coatings, paints, polymer sheets and tape, adhesives, and composites, for use in various spacecraft applications, including thermal control, structures, optics, and solar power. Since some subexperiments included duplicate samples exposed on the leading- and trailing-edge trays for 9-week, 19-week, 40-week, and 69-month durations, comparisons among samples provided a valuable time history of degradation. During the deintegration of the subexperiments from the M0003 trays, each sample was examined using bright-field, dark-field, and Nomarski-light microscopy techniques. Records of the condition of the samples and all available references of publication on postflight analyses on each sample were originally collected on a Macintosh computer database. In response to requests by the spacecraft community for a PC version of the database, two conversions were made: Paradox 4.0 and dBase IV. This report includes instructions for installation and use, including example searches and printouts, of each of these conversions. Copies of the electronic database are available on floppy disk by request in both IBM formats, as well as the original 4th Dimension for Macintosh version. DTIC

ASBESTOS CHARACTERIZATION USING SCANNING ELECTRON MICROSCOPY/LIGHT ELEMENT X RAY SPECTROMETRY
G. C. Fisher and R. M. Morchat Sep. 1993 23 p
(AD-A271611; DREA-TM-93/206) Avail: CASI HC A03/MF A01

The Defence Research Establishment Atlantic (DREA) has traditionally used scanning electron microscopy (SEM) coupled with energy dispersive x-ray (EDX) spectrometry to identify asbestos fibers in solid insulating materials. This analysis typically utilizes fiber morphology to determine the presence of asbestiform fibers and EDX analysis to characterize asbestos type. The characterization is accomplished by comparison of the relative amounts of magnesium, silicon, and iron present in the fibers. The EDX detector traditionally used in asbestos characterization employs a protective

beryllium shield that effectively blocks the passage of low energy x-rays. Thus characteristic x-rays from 'light elements' (those below sodium in atomic weight) are not detected. Recently, DREA acquired a commercial EDX detector that employs a polymer shield that allows for detection of x-rays from elements as low as boron in atomic weight. This report summarizes results of a study on the effects of using a light element detector on characterization of both asbestos standards and commercial asbestos-containing insulating material. The study showed that 'light element' SEM/EDX can be used to characterize asbestos fibers in bulk insulations. DTIC

MODEL FOR LIQUID BORON OXIDE DROPLET GASIFICATION IN H/O/C/F COMBUSTION ENVIRONMENTS Final Report, 1-30 Oct. 1992
R. C. Brown, C. E. Kolb, R. A. Yetter, F. L. Dryer, and H. Rabitz 11 Nov. 1992 57 p
(Contract N00014-92-C-0225)
(AD-A272911; ARI-RR-1045) Avail: CASI HC A04/MF A01

A model for the gasification of liquid boron oxide droplet in high temperature H/O/C/F environments is presented. The model includes a detailed gas phase reaction mechanism, multi-component molecular diffusion, and heterogeneous gas-surface reactions. The gas phase reaction mechanism consists of 103 reversible reactions for H/O/C, B/H/O/C, and B/H/O/C/F combustion systems. The surface reactions include processes that are first order in gas phase reactants and are thermodynamically competitive with vaporization. Model results are presented that illustrate the effect of variations in droplet diameter, gas phase temperature, composition, and oxygen to fluorine mole ratio. In addition, the model calculations are analyzed with reaction flux and gradient sensitivity analysis to determine the fastest and rate-limiting steps. Model results for several calculations indicate that the addition of fluorine accelerates the gasification process relative to B/H/O/C systems. The degree of enhancement, however, depends upon the temperature and composition of the surrounding gas and the droplet diameter. DTIC

ANALYSIS OF SEMI-INSULATING BULK GaAs USING GLOW DISCHARGE MASS SPECTROMETRY
Andrew E. Souzis, Richard T. Lareau, and Richard Wittstruck Aug. 1993 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273032; ARL-TR-69) Avail: CASI HC A03

The ability to perform sub-part per billion (ppb) analysis of semi-insulating (SI) GaAs substrate material is of critical importance for the development of electronic materials used in microelectronic device applications. Glow discharge mass spectrometry (GDMS) is commonly used to perform high sensitivity (part-per-trillion) measurements of metals and semiconductors. Since the sample is utilized as the cathode in a DC glow discharge, it must be conducting to some degree. Thus analysis of SI wafers presents major difficulties. Possible solutions include the use of a high purity mask or the mixing of pulverized sample material with high purity powder. Due to the finite purity of available materials, these methods have limitations. This study has resulted in the development of a novel method to perform maskless analysis of SI wafers with sub-ppb sensitivity across virtually the entire periodic table. This method has been utilized in various studies related to electronic device applications. DTIC

RADCAL: A NARROW-BAND MODEL FOR RADIATION CALCULATIONS IN A COMBUSTION ENVIRONMENT
W. L. Grosshandler Apr. 1993 57 p
(PB93-200889; NIST/TN-1402) Avail: CASI HC A04/MF A01

Radiation within a medium containing products of combustion is dependent upon the temperature and concentrations throughout the entire field. The energy is distributed across the infrared spectrum in a highly nonlinear fashion which greatly complicates modeling of the heat transfer within a burning environment. The report describes a numerical program, RADCAL, which predicts the radiant intensity leaving a nonisothermal volume containing nonuniform levels of carbon dioxide, water vapor, methane, carbon monoxide, nitrogen, oxygen, and soot. The absorption coefficient of the combined gases is calculated from a narrow-band model and a combination of tabulated spectral properties and theoretical approximations to the vibrational-rotational molecular bands. Soot is treated as a purely absorbing substance in the Rayleigh limit. Background on the development of the model, example calculations, and an explanation of input procedures are presented. NTIS

COMBUSTION IN TURBULENT JETS AND BUOYANT FLAMES Final Report, 1 Jan. 1990 - 31 Dec. 1992
P. E. Dimotakis and J. E. Broadwell 6 Apr. 1993 61 p See also PB92-211481
(Contract GRI-5087-260-1467)
(PB93-202372; GRI-93/0108) Avail: CASI HC A04/MF A01

Results from an investigation of the mixing mechanisms in liquid-phase and gas-phase jets are reported. The investigation addressed the effects of molecular diffusion rates (Schmidt number) and combustion heat release on these mechanisms and incorporated these mechanisms into modeling and predictive techniques for practical natural gas flames. The gas-phase, chemically reacting jet experiments in the High Pressure Combustion Facility investigated the effects of Reynolds number on turbulent jet diffusion flame length, free of buoyancy and radiation effects. In a collaborative modeling effort with the SANDIA CRF at Livermore, CA, the authors have made progress in incorporating the effects of radiation and buoyancy in their description of turbulent jet diffusion flames and make comparisons between their model results and some recent NO(x) measurements. A PROJECT ON PARAMETER IDENTIFICATION IN REACTION KINETICS
P. W. Hemker and J. Kok Jan. 1993 41 p Sponsored in part by AKZO Research Labs, Arnhem, Netherlands
(CWI-NM-R9301; ETN-94-94703) Copyright Avail: CASI HC A03/MF A01

A project to collect knowledge in parameter estimation, in order to be able to solve real life parameter estimation problems from chemical engineering is reported. A suitable method to solve these problems was found and a computer program was developed. These problems consist of a system of Ordinary Differential Equations (ODE's) or differential-algebraic equations containing parameters to be determined when experimental values are available that should fit the solution of the ODE's. By means of the program, several inverse problems for parameter estimation were solved. For the solution, the parameters and their range of probability were identified, and to what extent the information available from the experiments led to the possible identification of the parameters was determined. A summary of results is given and subjects for further research are identified. ESA

PLASMA-CHEMICAL CONVERSION OF HYDROGEN SULFIDE INTO HYDROGEN AND SULFUR
J. B. L. Harkness, R. D. Doctor, and E. J. Daniels 1993 8 p Presented at the 3rd World Congress on Engineering and Environment, Beijing, China, 12-14 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-31-109-eng-38)
(DE93-041167; ANL/ES/CP-80089; CONF-9310171-1) Avail: CASI HC A02/MF A01

A waste-treatment process that recovers both hydrogen and sulfur from hydrogen-sulfide-contaminated industrial wastes is being developed to replace the Claus technology, which recovers only sulfur. The proposed process is based on research reported in the Soviet technical literature and uses microwave (or radio-frequency) energy to initiate plasma-chemical reactions that dissociate hydrogen sulfide into elemental hydrogen and sulfur. In the plasma-chemical process, the gaseous stream would be purified and separated into streams containing the product hydrogen, hydrogen sulfide for recycle to the plasma reactor, and the process purge containing carbon dioxide and water. Since unconverted hydrogen sulfide is recycled to the plasma reactor, the plasma-chemical process has the potential for sulfur recoveries in excess of 99% without the additional tail-gas clean-up processes associated with the Claus technology. Laboratory experiments with pure hydrogen sulfide have confirmed that conversions of over 90% per pass are possible. Experiments with impurities typical of petroleum refinery and natural gas production acid gases have demonstrated that these impurities are compatible with the plasma dissociation process and do not appear to create new waste-treatment problems. Other experiments show that the cyclonic-flow pattern hypothesized by the Russian theoretical analysis of the plasma-chemical process can substantially decrease energy requirements for hydrogen sulfide dissociation while increasing conversion. This process has several advantages over the current Claus-plus-tail-gas-cleanup technology. The primary advantage is the potential for recovering hydrogen more cheaply than the direct production of hydrogen. The difference could amount to an energy savings of 40 x 10(exp 15) to 70 x 10(exp 15) J/yr in the refining industry, for an annual savings of $500 million to $1 billion. DOE

FEMTOSECOND DYNAMICS IN HYDROGEN-BONDED SOLVENTS
E. W. Castner, Jr. and Y. J. Chang 1993 14 p Presented at the Royal Netherlands Academy of Sciences Colloquium on Femtosecond Reaction Dynamics, Amsterdam, Netherlands, 16-19 May 1993
(Contract DE-AC02-76CH-00016)
(DE93-019937; BNL-49140; CONF-9305270-1) Avail: CASI HC A03/MF A01

We present results on the ultrafast dynamics of pure hydrogen-bonding solvents. The resutls were obtained using femtosecond Fourier-transform optical-heterodyne-detected, Raman-induced Kerr effect spectroscopy. The solvent systems we have studied include the formamides, water, ethylene glycol, and acetic acid. Inertial and diffusive motions are clearly resolved. We comment on the effect that such ultrafast solvent motions have on chemical reactions in solution. DOE

WATER-ENHANCED SOLVATION OF ORGANICS Ph.D. Thesis
J. H. Lee Jul. 1993 73 p
(Contract DE-AC03-76SF-00098)
(DE93-040297; LBL-34410) Avail: CASI HC A04/MF A01

Water-enhanced solvation (WES) was explored for Lewis acid solutes in Lewis base organic solvents, to develop cheap extract regeneration processes. WES for solid solutes was determined from ratios of solubilities of solutes in water-saturated and low-water solvent; both were determined from solid-liquid equilibrium. Vapor-headspace analysis was used to determine solute activity coefficients as function of organic phase water concentration. WES magnitudes of volatile solutes were normalized, set equal to slope of log gamma(sub s) versus x(sub w)/x(sub s) curve. From graph shape, Delta(log gamma(sub s)) represents relative change in solute activity coefficient. Solutes investigated by vapor-headspace analysis were acetic acid; propionic acid; ethanol; 1,2-propylene glycol; and 2,3-butylene glycol. Monocarboxylic acids had largest decrease in activity coefficient with water addition followed by glycols and alcohols. Propionic acid in cyclohexanone showed greatest water-enhancement Delta (log gamma(sub acid))/Delta(x(sub w)/x(sub acid)) = -0.25. In methyl cyclohexanone, the decrease of the activity coefficient of propionic acid was -0.19. Activity coefficient of propionic acid in methyl cyclohexanone stopped decreasing once the water reached a 2:1 water to acid mole ratio, implying a stoichiometric relation between water, ketone, and acid. Except for 2,3-butanediol, activity coefficients of the solutes studied decreased monotonically with water content. Activity coefficient curves of ethanol, 1,2-propanediol, and 2,3-butanediol did not level off at large water/solute mole ratio. Solutes investigated by solid-liquid equilibrium were citric acid, gallic acid, phenol, xylenols, and 2-naphthol. Saturation concentration of citric acid in anhydrous butyl acetate increased from 0.0009 to 0.087 mol/L after 1.3 % (g/g) water co-dissolved into organic phase. Effect of water-enhanced solvation for citric acid is very large but very small for phenol and its derivatives. DOE

DEVELOPMENT OF AN ELECTROCHEMICAL HYDROGEN SEPARATOR
S. Abens, J. Fruchtman, and A. Kush 1993 16 p Presented at the Coal-Fired Power Systems 1993 Advances in IGCC and PFBC Review Meeting, Morgantown, WV, 28-30 Jun. 1993
(Contract DE-AC21-89MC-26040)
(DE93-019877; DOE/MC-26040/93/C0220; CONF-9306148-24) Avail: CASI HC A03/MF A01

The EHS is an electrochemical hydrogen separator based on the uniquely reversible nature of hydrogen oxidation reduction reactions in electrochemical systems. Hydrogen from the mixed gas stream is oxidized to H(+) ions, transported through a cation transport electrolyte membrane (matrix) under an applied electric field, and discharged in a pure hydrogen state on the cathode. The cation transfer electrolyte membrane provides a barrier between the feed and product gases. The EHS design is an off-shoot of phosphoric acid fuel cell development. Although any proton transfer electrolyte can be used, the phosphoric acid based system offers a unique advantage because its operating temperature of approximately 200 C makes it tolerant to trace CO and also closely matches the water-shift reactor exit gas temperature (approximately 250 C). Hydrogen containing streams in coal gasification systems have large carbon monoxide contents. For efficient hydrogen recovery, most of the CO must be converted to hydrogen by the low temperature water-shift reaction. Advanced coal gasification and gas separation technologies offer an important pathway to the clean utilization of coal resources. DOE

COLUMN CHROMATOGRAPHIC SEPARATION OF Y(3+) FROM Sr(2+) BY POLYMERIC IONIZABLE CROWN ETHER RESINS
D. J. Wood, S. Elshani, C. M. Wai, R. A. Bartsch (Texas Technological Univ., Lubbock.), M. Huntley (Westinghouse Idaho Nuclear Co., Inc., Idaho Falls.), and S. Hartenstein (Westinghouse Idaho Nuclear Co., Inc., Idaho Falls.) 1993 22 p
(Contract DE-AC07-84ID-12435)
(DE94-000935; WINCO-11973) Avail: CASI HC A03/MF A01

Condensation polymers containing subunits of crown ether carboxylic acid monomers are effective stationary phases for the chromatographic separation of Y(3+) and Sr(2+). The pH range and metal loading capacities for the resins have been determined under equilibrium conditions. The resin can be regenerated for repeated use without losing its separation capability. Altering the molecular structure of the monomer (sym-dibenzo-16-crown-5-oxyacetic acid) by an alkyl substitution on the macrocyclic cavity decreases the loading capacity of the resin. DOE

INTERFACIAL REACTIONS BETWEEN TITANIUM AND BORATE GLASS
R. K. Brow, S. K. Saha (Lehigh Univ., Bethlehem, PA.), and J. I. Goldstein (Lehigh Univ., Bethlehem, PA.) 1992 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC04-76DP-00789)
(DE93-012847; SAND-92-2779C; CONF-930405-5) Avail: CASI HC A02/MF A01

Interfacial reactions between melts of several borate glasses and titanium were investigated by analytical scanning electron microscopy (ASEM) and x ray photoelectron spectroscopy (XPS). A thin titanium boride interfacial layer is detected by XPS after short (30 minutes) thermal treatments. ASEM analyses after longer thermal treatments (8-120 hours) reveal boron-rich interfacial layers and boride precipitates in the Ti side of the interface. DOE

GAMMA RAY SPECTROMETRY OF LDEF SAMPLES: RESULTS OF 1992 ANALYSES
W. G. Winn Sep. 1993 19 p
(Contract DE-AC09-89SR-18035)
(DE94-001177; WSRC-TR-93-430) Avail: CASI HC A03/MF A01

In January 1990, NASA retrieved the Long Duration Exposure Facility (LDEF), which had orbited the Earth since April 1984. The satellite had become slightly radioactive due to cosmic exposure, and the SRTC Underground Counting Facility was used to analyze LDEF samples of Al and Ta for activations of Na-22, Lu-172, and Lu-173. Background steel trunnion samples, not irradiated in space, were analyzed for Co-60. This report summarizes results for 15 samples analyzed in 1992. DOE

THEORETICAL PHASE DIAGRAMS FOR SOLID H(SUB 2)
M. P. Surh and K. J. Runge Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-001049; UCRL-JC-113403; CONF-930676-58) Avail: CASI HC A02/MF A01

Possible phase diagrams for solid molecular para-hydrogen in the 0-200 GPa pressure regime are constructed on the basis of ab initio calculations. Structures for the broken symmetry phase (BSP) and H-A phase have recently been proposed under the assumption that the molecules are centered on sites of a hexagonal close-packed lattice with the ideal c/a ratio, i.e., only molecular orientational and electronic changes are allowed. Symmetry considerations then dictate the simplest phase diagrams consistent with experimental observations, although the possibility of additional transitions cannot be ruled out. A simple model is introduced to describe the BSP and H-A transitions. DOE

INVESTIGATION OF AUSTENITIC ALLOYS FOR ADVANCED HEAT RECOVERY AND HOT GAS CLEANUP SYSTEMS
R. W. Swindeman 1993 16 p Presented at the 7th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 11-13 May 1993
(Contract DE-AC05-84OR-21400)
(DE93-017863; CONF-9305135-6) Avail: CASI HC A03/MF A01

Commercial and developmental alloys are evaluated in support of advanced steam cycle and combined cycle technology. Working with industrial groups, Grade 91 steel, which is a candidate for main steam line piping and superheater tubing in advanced steam cycle plants, is re-evaluated to examine metallurgical factors that influence long-time performance to 600 C. Deformation models and aging effect models are developed. Testing of corrosion-resistant filler metals for tubing is extended to times approaching 30,000 h. Good strengths are observed. Modified Type 310 stainless steels are examined to 927 C. It is found that these steels have up to twice the strength of standard Type 310H stainless steel. The behavior of aluminum-bearing alloys and high chromium alloys is examined for potential applications to 870 C. Thermal cycling of clad tubing is undertaken, and good performance is found. DOE

Maher (North Carolina State Univ., Raleigh.) Apr. 1993 4 p Presented at the Annual Meeting of the Electron Microscopy Society of America, Cincinnati, OH, 1-6 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019521; ANL/MSD/CP-79660; CONF-930822-8) Avail: CASI HC A01/MF A01

It has been claimed that effective Peierls stresses and mobilities of some dislocations in TiAl are influenced by anisotropy of bonding charge densities. This paper describes experiments conducted to verify these calculations. The experiments involved recording convergent beam electron diffraction patterns from a number of reflections, with the sample oriented at the Bragg condition. The rocking curves were matched. The deformation electron charge density distribution map for the (001) section is in good agreement with theory. DOE

SEGREGATION OF Si TO THE SURFACE OF Fe-29Ni-17Co ALLOY
G. C. Nelson and R. W. Buttry 1993 17 p Presented at the Minerals, Metals, and Materials Society/American Society for Metals (TMS/ASM) Materials Week 1992, Chicago, IL, 2-5 Nov. 1992
(Contract DE-AC04-76DP-00789)
(DE93-040053; SAND-93-1911C; CONF-9211117-11) Avail: CASI HC A03/MF A01

The segregation of Si impurities from the bulk to the surface of a low Cr Lot of Kovar (Fe-29Ni-17Co) has been investigated in order to determine the effects on the quality of the braze of Cu to these altered surfaces. It is found that oxides of Si are formed on the surface during wet hydrogen firing. Kinetics of this segregation process have been measured. DOE

N94-19904# Sandia National Labs., Albuquerque, NM.
NEAR ATOMIC RESOLUTION MICROANALYSIS OF INTERFACES BY ANALYTICAL ELECTRON MICROSCOPY
A. D. Romig, Jr. and J. R. Michael 1993 2 p Presented at the 3rd National Congress for Materials Science, Cancun, Mexico, 27 Sep. - 2 Oct. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019437; SAND-93-1756C; CONF-9309207-1) Avail: CASI HC A01/MF A01

High spatial resolution x-ray microanalysis in the analytical electron microscope (AEM) can be used to determine chemical composition on spatial scales of less than 50 nm. Simple scattering models have the drawback of being incapable of treating electron scattering in inhomogeneous specimens, such as at phase interfaces or grain boundary segregation. The best method for calculating electron scattering and x-ray generation function is by Monte Carlo methods. Two examples are discussed: a phase interface in an Fe-Ni-Cr alloy, and grain boundary segregation using a 0.3 nm Cu slab in a 25 nm Al film (the slab is parallel to incident electron beam). It is concluded that high spatial resolution x-ray microanalysis can achieve near atomic resolution, but that massively parallel Monte Carlo models for electron scattering and a well characterized electron beam are needed. DOE

N94-19922# Argonne National Lab., IL.
OXIDATION-REDUCTION INDUCED ROUGHENING OF PLATINUM (111) SURFACE
H. You and Z. Nagy Jun. 1993 8 p Presented at the 3rd International Conference on Surface X Ray and Neutron Scattering, Dubna, Russia, 24-29 Jun. 1993
(Contracts W-31-109-eng-38; DE-AC02-76CH-00016)

(DE93-017408; ANL/MSD/CP-80232; CONF-9306248-1) Avail: CASI HC A02/MF A01

Platinum (111) single crystal surface was roughened by repeated cycles of oxidation and reduction to study dynamic evolution of surface roughening. The interface roughens progressively upon repeated cycles. The measured width of the interface was fit to an assumed pow law, W approximately = t(exp beta), with beta = 0.38(l). The results are compared with a simulation based on a random growth model. The fraction of the singly stepped surface apparently saturates to 0.25 monolayer, which explains the apparent saturation to a steady roughness observed in previous studies. DOE

RAPID HEATING TENSILE TESTING UPDATE: 304L STAINLESS STEEL

W. C. Mosley 1993 9 p Presented at the 1993 Meeting of the Interagency Manufacturing Operations Group on Mechanical Testing, Livermore, CA, 20-22 Jul. 1993
(Contract DE-AC09-89SR-18035)
(DE93-018770; WSRC-MS-93-404; CONF-9307121-1) Avail: CASI HC A02/MF A01

In stainless steel equipment exposed to tritium, embrittlement is thought to involve interactions between internal He and the complex triaxial stress state that arises when necking starts. Recent efforts have been directed at determining He concentration thresholds for this effect in several austenitic stainless steels. This report describes results of tests on 304L stainless steel containing low He-3 contents. 304L stainless steel containing 0.47 and 4.1 appm He-3 tested at 803-814 C had lower tensile properties than uncharged samples. Mechanical properties were not affected by 0.47 appm at 615 C but ductility was severely decreased at 810 C. DOE

N94-19944# Sandia National Labs., Albuquerque, NM.

SHOCK RESPONSE OF POROUS Al-2 + Fe2O3 POWDER MIXTURES

G. T. Holman, Jr., R. A. Graham, and M. U. Anderson 1993 4 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018851; SAND-93-0422C; CONF-930676-41) Avail: CASI HC A01/MF A01

Time-resolved pressure measurements have been conducted on Al-2 + Fe2O3 powder mixtures using the (PVDF) stress-rate gauge. These measurements were made on samples which were 53% of solid density. Measurements were made at pressures from 0.67 to more than 10 GPa utilizing both impact loading with a compressed gas gun and direct contact high explosive loading. The sample is pressed to the desired density in a copper capsule. PVDF gauges were positioned in front of and behind the powder sample in direct contact with the sample; they measure input and propagated stress-rate and are used for precise measurement of velocity through the 4 mm thick sample. In the case of high explosive loading, gauges are also installed on the explosive side and on the capsule side of a metal driver plate to measure the shock velocity through the driver so that the driver pressure can be determined. The response of Al-2 + Fe2O3 under shock compression appears to demonstrate a more complex behavior than other materials. At approximately 4.6 GPa, the material compresses to beyond solid density. There was no evidence of chemical reaction. DOE

INVESTIGATION OF CRACKING AND ERRATIC BEHAVIOR OF THE URANIUM-TITANIUM ALLOY

E. L. Bird Jul. 1993 17 p Presented at the International Metallographic Society Meeting, Charleston, SC, 18-21 Jul. 1993
(Contract DE-AC05-84OS-21400)
(DE93-018591; Y/DV-1227; CONF-9307118-1) Avail: CASI HC A03/MF A01

The uranium-0.8 wt % titanium (U-0.8 Ti) alloy is often used in weapon applications where high strength and fairly good ductility are necessary. Components are immersion quenched in water from the gamma phase to produce a martensitic structure that is amenable to aging. Undesirable conditions occur when a component occasionally cracks during the quenching process, and when tensile specimens fail prematurely during mechanical testing. These two failures prompted an investigative analysis and a series of studies to determine the causes of the cracking and erratic behavior observed in this alloy. Quench-related failures whereby components that cracked either during or immediately after the heat treatment/quenching operation were sectioned for metallographic examination of the microstructure to examine the degree of phase transformation. Examination of premature tensile specimen failures by scanning electron microscopy and x-ray imaging of fracture surfaces revealed pockets of inclusions at the crack origins. In addition, tests were conducted to evaluate the detrimental effects of internal hydrogen on ductility and crack initiation in this alloy. DOE

MICROSCOPIC ORIGINS OF METASTABLE EFFECTS IN a-Si:H AND DEEP DEFECT CHARACTERIZATION IN a-Si,Ge:H ALLOYS

J. D. Cohen Aug. 1993 23 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-018205; NREL/TP-451-5737) Avail: CASI HC A03/MF A01

This report describes work to evaluate low-mobility-gap a-Si,Ge:H alloy films. Results are based on junction capacitance techniques of admittance spectroscopy, transient photocapacitance (and photocurrent), and drive-level capacitance profiling. Eight a-Si,Ge:H alloy samples grown by photo-CVD encompassed the range of optical gaps from 1.3 to 1.6 eV, and corresponding Ge fractions from about 20 to 60 at%. We employed junction capacitance techniques to determine deep defect energies and densities, Urbach band-tail energies, and (mu)(tau) products for holes. Electron microprobe analysis provided accurate Ge fractions for our samples, thus enabling us to establish clear trends in measured electronic properties vs Ge fraction. We concluded that these photo-CVD samples exhibited equal or superior properties in terms of band-tail widths and stable defect densities compared to any reported results on a-Si,Ge:H samples grown by glow discharge. By assigning defect energy levels from analysis of transient subband-gap photocapacitance and photocurrent spectra, we found clear evidence for two distinct defect subbands, one at roughly midgap and the other in the upper half of the gap. The trapping lifetime related (mu)(tau) products for holes decreased in direct proportion to the density of mid-gap defects in these samples. This appears to be the case regardless of whether we are dealing with stable defects or defects created by light-soaking. DOE

N94-19986# Lawrence Livermore National Lab., CA.

MAGNETIC CIRCULAR DICHROISM IN X RAY ABSORPTION AND CORE-LEVEL PHOTOEMISSION

J. G. Tobin, G. D. Waddill, T. H. Gouder, C. A. Colmenares, and D. P. Pappas (Naval Research Lab., Washington, DC.) 17 Mar. 1993 8 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE93-019381; UCRL-JC-113366; CONF-930405-37) Avail: CASI HC A02/MF A01

Here is reported observation of magnetic circular dichroism in both x-ray absorption and core-level photoemission of ultra thin magnetic films using circularly polarized x-rays. Iron films (1 - 4 ML) grown on a Cu(001) substrate at 150 K and magnetized perpendicular to the surface show dramatic changes in the L(sub 2,3) branching ratio for different x-ray polarizations. For linearly-polarized x-rays perpendicular to the magnetic axis of the sample the branching ratio was 0.75. For films greater than or equal to 2 ML, this ratio varied from 0.64 to 0.85 for photon spin parallel and anti-parallel, respectively, to the magnetic axis. This effect was observed either by changing the x-ray helicity for a fixed magnetic axis or by reversing the magnetic axis for a fixed x-ray helicity. Our observation can be analyzed within a simple one-electron picture, if the raw branching ratios are normalized so that the linear value becomes statistical. Furthermore, warming the films to approximately 300 K eliminated this effect, indicating a loss of magnetization in the film over a temperature range of approximately 30 K. Finally, reversing the relative orientation of the photon spin and the magnetic axis from parallel to anti-parallel allowed measurement of the exchange splitting of the Fe 2p and 3p core levels which were found to be 0.3 eV and 0.2 eV, respectively. These results are consistent with earlier studies, but the use of off-plane circularly-polarized x-rays from a bending magnet monochromator offers approximately 2 orders of magnitude greater intensity than typical spin-polarization measurements. Finally, we have performed

preliminary x-ray absorption studies of UFe2, demonstrating the feasibilty of MCD measurements in 5f as well as 3D materials. DOE

HIGH PERFORMANCE HEAVY ALLOYS BY ALLOYING AND PROCESS CONTROL Final Report, 15 Aug. 1991 - 14 May 1993
A. Belhadjhamida and R. M. German 22 Jun. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0309)
(AD-A271129; ARO-29326.14-MS) Avail: CASI HC A03

The kinetics and processing conditions of liquid phase sintering (LPS) have been addressed in the development of a novel heavy alloy, W-Ni-Mn. Solubility criteria were considered in the selection of manganese as an alloying element to the W-Ni system. The addition of manganese resulted in a depressed melting point of the matrix, and consequently, sintering in this system was achieved at temperatures 300 C lower than in the conventional heavy alloys. Concurrent with solubility criteria, the rearrangement stage in liquid phase sintering was treated. When capillary and viscous drag forces are accounted for, the time scales in rearrangement were found to be in the microseconds range for metal systems. On the other hand, heat transfer was found to be the rearrangement time limiting factor for metallic specimens with time scales in the range of seconds. Further, depending on the Green density and the system under consideration, there exists specific specimen dimensions where a transition from heat transfer to capillary control over the rearrangement time. These dimensions are, however, in the micrometer range. DTIC

EVALUATION OF A DIFFUSION/TRAPPING MODEL FOR HYDROGEN INGRESS IN HIGH-STRENGTH ALLOYS Final Report, 15 Sep. 1991 - 14 Sep. 1993
Bruce G. Pound Oct. 1992 80 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-C-0263)
(AD-A271328) Avail: CASI HC A05

Alloys developed to improve strength, weight, and corrosion resistance often remain susceptible to hydrogen embrittlement (HE). The objective of this research was to investigate hydrogen ingress in high performance alloys, particularly in terms of irreversible trapping, with a view to characterizing their susceptibility to HE. A technique referred to as hydrogen ingress analysis by potentiostatic pulsing (HIAPP) was applied to five unaged and aged B-Ti alloys (Beta-C, Ti-10-2-3, Ti-13-11-3, Ti-15-3, and Beta-21S), an alpha-beta Ti alloy (Ti-6-4), two Cu-Ni alloys (Marinel and Monel K-500), and a Ni-base alloy (UNS N07716). Anodic transients obtained in 1 mol/L HAc-l mol/L NaAc (Ac = acetate) were analyzed using a diffusion/trapping model to evaluate the trapping constant and hydrogen entry flux. Except for Ti-15-3, aging increases irreversible trapping in the B-Ti alloys, the increase parallels the decrease in their tolerance to hydrogen. Ti-13-11-3 is indicated to be the most susceptible to HE, followed by Beta-21S, Beta-C, Ti-10-2-3, and Ti-15-3, with the trapping constants apparently being determined by the degree of grain boundary alpha phase. The trapping constants for aged Marinel and alloy K-500 do not appear to differ significantly, but a lower flux for Marinel accounts, at least partly, for its higher resistance to HE. Likewise, a low flux for alloy 716 is consistent with it generally being resistant to cracking. DTIC

EFFECTS OF PROCESSING HISTORY ON THE CREEP STRENGTH OF Nb-1Zr
J. A. Horak and L. K. Egner 1993 6 p Presented at the Joint MMIJ/TMS International Conference on Processing Materials for Properties, Honolulu, HI, 7-10 Nov. 1993
(Contract DE-AC05-84OR-21400)
(DE93-015905; CONF-931103-1) Avail: CASI HC A02/MF A01

Power systems that are used to provide electrical power in space are designed to optimize conversion of thermal energy to electrical energy and to minimize the mass and volume that must be launched. Only refractory metals and their alloys have sufficient long-term strength for several years of uninterrupted operation at the temperatures required (e.g., greater than 1200 K). The high power densities and temperatures at which these reactors must operate require the use of liquid-metal coolants. The alloy Nb-1 wt % (Nb-1Zr), which exhibits excellent corrosion resistance to alkali liquid-metals at high temperatures, is being considered for the fuel cladding, reactor structural, and heat transport systems for current space exploration missions. Useful lifetimes of these power systems are limited by creep deformation in the reactor core. Nb-1Zr sheet procured to American Society for Testing and Materials (ASTM) specifications for reactor grade and commercial grade has been processed by several different cold work and annealing treatments to attempt to produce the grain structure (size, shape, and distribution of sizes) that provides the maximum creep strength of this alloy at temperatures from 1250 to 1450 K. The effects of grain size, differences in oxygen concentrations, tungsten concentrations, and electron beam and gas tungsten arc weldments on creep strength were studied. Grain size has a large effect on creep strength at 1450 K but much less of an effect at 1350 K. Differences in oxygen or tungsten concentrations did not affect creep strength, and the creep strengths of weldments were equal to, or greater than, those for base metal. DOE

MICROSTRUCTURAL STABILITY OF WROUGHT, LASER AND ELECTRON BEAM GLAZED NARloy-Z ALLOY AT ELEVATED TEMPERATURES
J. Singh, G. Jerman, B. Bhat, and R. Poorman Nov. 1993 37 p Sponsored by NASA. Washington
(NASA-TM-108431; NAS 1.15:108431) Avail: CASI HC A03/MF A01

Microstructure of wrought, laser, and electron-beam glazed NARloy-Z(Cu-3 wt.% Ag-0.5 wt.% Zr) was investigated for thermal stability at elevated temperatures (539 to 760 C (1,100 to 1,400 F)) up to 94 h. Optical and scanning electron microscopy and electron probe microanalysis were employed for studying microstructural evolution and kinetics of precipitation. Grain boundary precipitation and precipitate free zones (PFZ's) were observed in the wrought alloy after exposing to temperatures above 605 C (1,120 F). The fine-grained microstructure observed in the laser and electron-beam glazed NARloy-Z was much more stable at elevated temperatures. Microstructural changes correlated well with hardness measurements. Author (revised)

HYDROGEN PICKUP AND REDISTRIBUTION IN ALPHA-ANNEALED ZIRCALOY-4
B. F. Kammenzind, D. G. Franklin, W. J. Duffin, and H. R. Peters (General Electric Co., Schenectady, NY.) Jul. 1993 31 p Presented at the Electric Power Research Institute Utility-industry Workshop on Pressurized-Water Reactor Fuel Rod Corrosion, Washington, DC, 28-30 Jul. 1993
(Contract DE-AC11-89PN-38014)
(DE93-018050; WAPD-T-3010; CONF-9307115-1) Avail: CASI HC A03/MF A01

Zircaloy-4, which is widely used as a core structural material in Pressurized-Water Reactors (PWR), picks up hydrogen during service. Hydrogen solubility in Zircaloy-4 is low and hydrides precipitate after the Zircaloy-4 matrix becomes slightly supersaturated with hydrogen. These hydrides embrittle the Zircaloy-4. To study hydrogen pickup and concentration

a postirradiation nondestructive radiographic technique for measuring hydrogen concentration was developed and qualified. Experiments on hydrogen pickup were conducted in the Advanced Test Reactor (ATR). Out-of-pile tests were conducted to determine the conditions for which hydrogen would migrate. Finally, a phenomenological model was built and indexed to the data. This presentation describes the experiments and the model, presents the results of experiments, and compares the model predictions to experimental results. DOE

Fine alumina powders of spherical morphology and narrow particle-size distribution have been synthesized by a technique that uses precipitation/peptization/spray drying of boehmite sol-prepared from aluminum nitrate. The spray-dried powder was further washed with solvents of varying polarities, such as acetone, isopropanol, and tert-butanol. This post-spray-drying treatment changed the powder's particle-size distribution, morphology, density, and compaction characteristics. Microstructure, dielectric properties, and effect of post-treatment on the boehmite-sol-derived alumina powders in reducing agglomeration are discussed. DOE

FUNDAMENTALS OF MECHANICAL BEHAVIOR IN STRUCTURAL INTERMETALLICS: A SYNTHESIS OF ATOMISTIC AND CONTINUUM MODELING
M. H. Yoo and C. L. Fu 1993 10 p Presented at the International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE93-019166; CONF-930997-4) Avail: CASI HC A02/MF A01

After a brief account of the recent advances in computational research on mechanical behavior of structural intermetallics, currently unresolved problems and critical issues are addressed and the knowledge base for potential answers to these problems is discussed. As large-scale problems (e.g., dislocation core structures, grain boundaries, and crack tips) are treated by atomistic simulations, future development of relevant interatomic potentials should be made consistent with the results of first-principles calculations. The bulk and defect properties calculated for intermetallic compounds, both known and as yet untested, can furnish insights to alloy designers in search of new high-temperature structural intermetallics. PROPERTIES AND POTENTIAL OF HIGH-TEMPERATURE NIOBIUM BERYLLIDES
S. M. Bruemmer, J. L. Brimhall, C. H. Henager, Jr., and J. P. Hirth (Washington State Univ., Pullman.) Dec. 1992 6 p Presented at the 16th Materials Research Society Fall Meeting, Boston, MA, 30 Nov. - 5 Dec. 1992
(Contract DE-AC06-76RL-01830)
(DE93-019169; PNL-SA-21290; CONF-921101-137) Avail: CASI HC A02/MF A01

Recent research on the low- and high-temperature properties of two beryllium-niobium intermetallic compounds, Be12Nb and Be17Nb2, is reviewed and discussed. Strength (bend and compression), hardness and fracture toughness has been mapped as a function of test temperature up to 1200 C. Results for hot-isostatically-pressed Be12Nb and Be17Nb2 are highlighted illustrating the potential for reasonable strength at both low and high temperatures. Limitations for structural use of the beryllides are identified and discussed including low-temperature toughness, intermediate-temperature embrittlement, high-temperature creep strength and composite compatability. MICROSCOPIC EVALUATION OF LOW-TEMPERATURE EMBRITTLEMENT IN TYPE 308 STAINLESS STEEL WELDS
J. M. Vitek, S. A. David, and D. J. Alexander 1993 11 p Presented at the International Metallographic Society Meeting, Charleston, SC, 18-21 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE93-040266; CONF-9307118-2) Avail: CASI HC A03/MF A01

Effect of aging of type 308 stainless steel weld metal from 400 to 550 C on microstructure was examined. Microstructural development was correlated with earlier results on mechanical properties that showed the ferrite-containing welds were prone to severe embrittlement when aged in this temperature range. The embrittlement was manifested by an increase in the ductile-brittle transition temperature and a drop in the upper-shelf energy. It was found that although the embrittlement over this aging temperature range was comparable, the microstructural changes that were responsible for the embrittlement were different at different temperatures. Embrittlement was caused by a combination of spinodal decomposition of ferrite, precipitation of M23C6 carbide at the ferrite/austenite interface, and G-phase precipitation within the ferrite. Sigma phase formation at 550 C may also be a contributing factor to the embrittlement. DOE

NEUTRAL COPPER CLUSTER SPUTTERING YIELDS: Ne(+), Ar(+) AND Xe(+) BOMBARDMENT
S. R. Coon, W. F. Calaway, and M. J. Pellin 1993 15 p Presented at the 15th International Conference on Atomic Collision in Solids, London, Ontario, 26-30 Jul. 1993
(Contract W-31-109-eng-38)
(DE93-019010; ANL/CHM/CP-80470; CONF-930712-3) Avail: CASI HC A03/MF A01

The sputtering of neutral metal clusters was investigated by measuring relative sputtering yields of copper clusters ejected from polycrystalline copper under 3.9 keV bombardment by Ne(+), Ar(+) and Xe(+) ions at normal incidence. Yields of clusters from Ne(+) bombardment were lower than those from Ar(+) bombardment, were lower than from Xe(+) bombardment. Sputtering yield ratios Ne(+)/Ar(+) and Xe(+)/Ar(+) were 0.56 and 1.08. Size distribution of sputtered clusters can be fit by a power law dependence with exponents of -8.1, -8.2 and -6.2 for Ne(+), Ar(+) and Xe(+), respectively. The similarity of the exponents of the Ne(+) and Ar(+) power law fits indicates that the sputtering yields for these two primary ions are similar while that for Xe(+) is substantially higher, in contrast to the sputtering yield ratio data. The difference between the two measurements can be explained by assuming a systematic uncertainty in the sputtering yield ratio measurements that makes the measured ratios lower than the true values. Assuming a value at the high end of the experimental Ne(+) sputtering yield range, the exponents of the power law fits exhibit a linear dependence on the total sputtering yield. DOE

THE USE OF X RAY TECHNIQUES IN THE IN SITU STUDY OF CORROSION
H. S. Isaacs 1992 16 p Presented at the NATO Advanced Research Workshop, Maderia, Portugal, Dec. 1992
(Contract DE-AC02-76CH-00016)
(DE93-019845; BNL-49361; CONF-921277-2) Avail: CASI HC A03/MF A01

Applications of x-ray absorption and fluorescence techniques for in situ chemistry studies of passivity and localized corrosion have been described. X-ray absorption near edge structures showed that rapidly grown oxides on aluminum-chromium alloys incorporated chromium in the oxide. Repeated electrochemically induced changes between the chromium 3- and 6-valent state occurred without chromium dissolving. When the oxide was grown by small potential steps, the chromium dissolved when 6-valent chromate was formed. With iron-chromium alloys, dissolution of chromate took place, but 6-valent chromium was also incorporated in the oxide. The 6-valent state was reduced on exposing the iron alloy to air. X-ray fluorescence measurements, in conjunction with energy dispersive analysis, have been used to monitor iron, chromium, and nickel concentrationsin

solution. The concentrations and concentration gradients during localized corrosion of stainless steel were used to determine salt solubility and relative diffusion rates. DOE

TEMPERATURE DEPENDENCE OF 4f PES FEATURES AND HOLE OCCUPANCY IN YTTERBIUM HEAVY FERMIONS
A. B. Andrews, R. I. R. Blyth, and A. J. Arko et al 1993 8 p Presented at the International Conference on Strongly Correlated Electron Systems, La Jolla, CA, 16-19 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE93-040131; LA-UR-93-3014; CONF-930865-10) Avail: CASI HC A02

The authors have measured the temperature dependence between 80 and 300 K and spectral weight of the 4f features in clean single crystal Yb heavy fermions, cleaved in a vacuum of 5 x 10(exp -11) Torr. A small (approximately 10%) decrease in spectral weight differs substantially from the reported approximately 50% decrease over this range. All divalent features are much larger than expected, yielding n(sub f) values far too small. The intensity of the divalent features in YbAuCu4 is about two orders of magnitude larger than expected. CRATERING EVALUATIONS AND RESULTS
J. R. Church Aug. 1993 29 p
(Contract DE-AC04-76DP-00613)
(DE93-040347; KCP-613-5111) Avail: CASI HC A03/MF A01

Investigations were performed on the 1-mil ultrasonic aluminum wire bonding process to determine how the interaction of the bonding parameters, ultrasonic power, time, force, and aluminum wire, contribute to cratering (cracking or damage to oxide/passivation layers). Investigations revealed that power, time, and force can interact at levels which can contribute to cratering. The age of the aluminum wire can also influence the quality of bonds. DOE

Mechanical alloying is a solid state process which can be used to synthesize various compounds. By mechanical alloying nanocrystalline, microcrystalline, crystalline, and amorphous materials can be produced. Wider solubility ranges can be obtained and the properties of materials can be varied more easily than by conventional methods. In addition, the process is less expensive and simpler than the methods that are used nowadays. It can be applied in producing new construction materials, magnets, copper alloys, hydrogen storage materials, and super conductors. The method makes the dispersion strengthening possible already during alloying. Also, the particle size can be controlled. The results of the alloying of nickel and titanium aluminum by mechanical alloying are presented. Aluminum alloys have many applications, for example in process industry and as tool materials because of their good corrosion resistance and excellent high temperature strength properties. They also offer good strength/weight ratio. Both nickel and titanium were alloyed with aluminum using many various concentration ratios. The alloys were examined by scanning electron microscope, X-ray diffractometer and differential scanning calorimeter. According to the X-ray diffraction both nickel and titanium aluminides were synthesized, i.e. the alloy consisted of chemical compound. Some samples were amorphous. The particle size varied in different samples. At smallest it was of the order of 1 micrometer. ESA

WELDALITE (TM) 049 (Al 2095-T8): ANISOTROPY EFFECTS AT CRYOGENIC CONDITIONS Interim Report, Aug. 1991 - Jun. 1993
John J. Ruschau and Kumar V. Jata Aug. 1993 36 p
(Contract F33615-90-C-5915)
(AD-A272658; UDR-TR-93-69; WL/ML-TR-93-4096) Avail: CASI HC A03/MF A01

Tensile, fracture, and FCGR testing was performed on a plate of the aluminum-lithium alloy Weldalite(TM) 049 (Al 2095-T8) over a temperature range from ambient to liquid helium (4K) conditions. Properties were developed on specimens removed from various orientations within a 12.7 mm (1/2 in) nominal thick plate to characterize anisotropy with respect to strength and toughness. Strength and FCGR properties are compared to the conventional aluminum alloy 2219-T87, developed for similar cryogenic applications. Results indicate a high degree of anisotropy with respect to strength and ductility, with the lowest strength/highest ductility occurring at 45-60 deg from the rolling direction. Decreases in test temperature led to higher strengths and similar anisotropic behavior, with little or no change in ductility. Fracture toughness measurements did not reveal any significant orientation effects, with toughness levels insensitive to the cryogenic temperatures examined. It was not possible to develop valid FCGR data on C(T) samples oriented in either the T-L or T-L plate directions due to out-of-plane cracking. Constant amplitude FCGR data generated on 45 deg oriented samples are comparable with reference data on similar Weldalite material for the T-L and L-T directions, though a slight degree of anisotropy appears to exist at lower values of Delta K. FCGR data obtained at liquid nitrogen and liquid helium test conditions were identical and only slightly lower than similar data developed under ambient conditions. DTIC

The essence of this Air Force Office of Scientific Research (AFOSR) project is to investigate the structure, composition, mode of attachment, and reactivity of the molecular species which form at the surfaces of metals in contact with fluids. Progress to date includes advances in investigative technology, 110 scientific articles, and useful findings as follows: a series of new findings, advances in investigative technology and 105 scientific articles have occurred thus far. These include (1) determination of molecular orientations and modes of attachment at electrode surfaces; (2) demonstration that mode of surface attachment affects electrochemical reactivity; (3) exploration of the structure and composition of electrodeposited metal monolayers and thin-films; (4) investigation of the nature of the species formed at electrode surfaces in ionic solutions; (5) adaptation of high-resolution electron energy-loss spectroscopy (HREELS) to measurement of vibrational spectra of species adsorbed at electrode surfaces; (6) systematic HREELS, Auger and electrochemical studies of families of adsorbates, including acids, alcohols, alkenes, amines, mercaptans, phenols, and pyridines; (7) demonstration of the stability of chemisorbates in vacuum; (8) development of techniques for measurement of complete Auger emission angular distributions potentially useful for structure probing of solid surfaces; (9) development of an infrared (IR) reflectance spectrometer capable of recording the vibrational spectra of typical adsorbed organic molecules; and (10) studies of the interaction of the polar solvent acetonitrile with solid electrode surfaces. Microstructural evolution during thermomechanical processing of several

Al-Mg alloys was studied using backscattered orientation contrast imaging in the scanning electron microscope. The microstructural evolution in AlMg8Zr(0.1) was characterized in three phases: in the initial stages, precipitation occurred on prior boundaries and microbands were observed in the grain interiors; during intermediate stages, higher order microbands were observed and precipitates formed throughout the microstructure on both lower- and higher-order microbands; and in the final stages, equiaxed regions appeared around larger particles suggesting particle stimulated nucleation of recrystallization. A higher Mg-content alloy (AlMg10Zr(0.1)) was compared at two stages and seen to provide a greater volume fraction of similar sized precipitate. A finer recrystallized microstructure and greater superplastic response was observed in the AlMg10Zr(0.1) alloy. DTIC

The constitution of Fe3(AlSi) based alloys was examined by means of transmission electron microscopy and x ray powder diffraction on quenched samples. Critical temperatures for DO3-order as well as the ranges of the several miscibility gaps between the alpha solid solution and the ordered phases alpha' (B2 structure) alpha'' (DO3 structure) were determined in alloys with 80, 75, and 70 at% iron. The critical temperatures were used to calculate the interaction and antiphase boundary energies within the framework of thre Bragg-Williams approximation. The morphology of the two phase microstructures and the nucleation behavior in the ordered alloys are discussed. Additionally the dislocation structures in Fe70Al30 single crystals deformed at different temperatures were investigated by electron microscopy and the results were compared to existing models to explain the temperature dependence of the yield strength. The HIP processing of MoSi2 and MoSi2 + Nb powder, Nb wire, and Nb foil composites was optimized. The reaction between MOSi2 and Mo, W, Ta, and Nb reinforcements at 1700 C was examined. W, Ta, and Nb reinforcements formed complex, two layer reaction zones in contact with MoSi2. Reaction layer growth parameters were measured for Nb. Detailed HIP modeling and deformation mechanism mapping was carried out for MOSi2, MoSi2 + Nb, and MoSi2 + SiC. The results indicate 1400-1500 C to be optimal for producing greater than 98% dense material. A sensitivity analysis was developed and demonstrated for HIP modeling of TiAl and MOSi2. Bend strengths of MoSi2, MoSi2 + Nb powder, MOSi2 + 250 micrometer Nb wire, MoSi2 + 750 micrometers wire, and 200 micrometer Nb foil were measured between 20 and 1450 C in vacuum. Compositing with Nb significantly lowered elevated temperature strength. K(sub 1c) was measured at 20 C for each composite and significant improvements were observed. Reinforcement morphology had a strong effect on toughness. Reinforcement morphologies listed in order of increasing potency are: Nb powder, 250 micrometer Nb wire, 750 micrometer Nb wire, and Nb foil. Quantitative comparison was made between theory and measurement of the toughness increase, and poor agreement was found. HIP reaction of MoSi2 and Ti powder was explored. DTIC

LASER RAMAN AND X RAY SCATTERING STUDIES OF CORROSION FILMS ON METALS
C. A. Melendres Feb. 1993 10 p Presented at the 12th International Corrosion Congress, Houston, TX, 19-24 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-040243; ANL/CMT/CP-79337; CONF-9309150-6) Avail: CASI HC A02/MF A01

Optical spectroscopic and x ray scattering techniques, coupled with electrochemical methods, are among the most useful in probing the structure of corrosion films on metals in-situ in aqueous environments. Laser Raman spectroscopy has been employed for a number of years to investigate composition of surface films on metals like iron, nickel, chromium, and stainless steel. Our work is illustrted by presenting some results of studies of composition of passive film on nickel, using surface enhanced Raman scattering (SERS) with an electrodeposited silver overlayer. It was found that both oxide and hydroxide species are present on the surface of Ni in the passive region. The utility of specular x ray reflection in providing complementary information on the physical structure of passivated metal surfaces was also demonstrated. Thickness of the corrosion films formed, density of surface layers, and development of surface and interface roughness on Cu electrodes were quantitatively monitored in-situ as a function of potential for the first time. EXPERIMENTAL STUDY OF VOID FORMATION DURING ALUMINUM SOLIDIFICATION IN REDUCED GRAVITY Ph.D. Thesis - Toledo Univ.
Francis Paul Chiaramonte, III Oct. 1993 78 p
(RTOP 674-24-05)
(NASA-TM-106190; E-7520-1; NAS 1.15:106190) Avail: CASI HC A05/MF A01

Void formation due to volumetric shrinkage and liquid/vapor reorientation during aluminum solidification was observed in real time by using a radiographic viewing system in normal and reduced gravity. An end-chill directional solidification furnace with water quench was designed and constructed to solidify aluminum samples during the approximately 16 sec of reduced gravity (+/-0.02g) achieved by flying an aircraft through a parabolic trajectory. In the first series of tests the aluminum was contained in a vacuum sealed, pyrolytic boron nitride crucible. An ullage space was present during each test. Void formation was recorded for two cases: a nonwetting system, and a wetting system where wetting occurred between the aluminum and the crucible lid. The void formation in the nonwetting case was similar in normal and reduced gravity, with a single vapor cavity forming at the top of the crucible. In the wetting case during reduced gravity surface tension caused two voids to form in the top corners of the crucible, but during normal gravity only one large void formed across the top. In the second series of tests the aluminum was contained in a pyrolytic boron nitride crucible that was placed in a stainless steel container and sealed in an environment of argon plus 4 percent hydrogen. An ullage space was present during each test. Void formation was recorded for two cases: a nonwetting system, and a wetting system where wetting occurred between the aluminum and one side wall and the lid. The void for nation in the nonwetting case was similar in normal and reduced gravity, with a single vapor cavity forming at the top of the crucible, although the meniscus became more convex in reduced gravity. In the wetting case the aluminum

did not climb up the corners in 1g, and one large symmetric void resulted at the top when the aluminum had solidified. In the wetting case during reduced gravity the molten aluminum was drawn up the wetted wall and partially across the lid by a capillary underpressure; however, on the nonwetting wall the aluminum moved down. One void resulted along the nonwetting side of the container continuing to the top on the same side.

STATIC ULTRA-HIGH PRESSURE STUDY OF LANTHANIDE AND ACTINIDE METALS USING A DIAMOND-ANVIL CELL
J. Akella, G. S. Smith, and S. T. Weir 30 Jun. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-000369; UCRL-JC-114166; CONF-930676-52) Avail: CASI HC A02/MF A01

Structural phase transformation in lanthanides and actinides were investigated as a function of pressure up to 300 GPa at room temperature. Except in Ce and Pr, no large volume changes were noticed for these metals as they went through several phase changes. The appearance of a bct ultra-high pressure phase in Ce, Sm, Th, and possibly in Np, raises the possibility that the ultimate high pressure structure for the 4f and 5f metals may be the bct structure. On the other hand, it is also possible that this is a precursor to another close-packed structure at even higher pressure.

EVALUATION OF THE FABRICABILITY OF ADVANCED IRON ALUMINIDE-CLAD AUSTENITIC STAINLESS STEEL TUBING
W. R. Mohn and M. J. Topolski Jul. 1993 42 p Prepared in cooperation with Babcock and Wilcox Co., Alliance, OH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE93-040598; ORNL/Sub-88-SB775/03) Avail: CASI HC A03

Researchers at Babcock & Wilcox Alliance Research Center have investigated methods to produce bimetallic tubing consisting of iron aluminide-clad austenitic stainless steel for practical use in fossil fueled energy equipment. In the course of this work, the compatibility of iron aluminide with four candidate austenitic stainless steel substrates was first evaluated using diffusion couples. Based on these results, a combination of iron aluminide and 304 stainless steel was selected for further development. Two composite billets of this combination were then prepared and extruded in separate trails at 2200 and 2000 F. Both extrusions yielded 2-inch OD clad tubes, each approximately 18 feet long. Results of the evaluation show that the tube extruded at 2000 F had a sound, integrally bonded clad layer throughout its entire length. However, the tube extruded at 2200 F exhibited regions of disbonding between the clad layer and the substrate. In supplement to this work, an assessment of the technical and economic merits of iron aluminide-clad austenitic stainless steel components in power generation systems was conducted by B&W Fossil Power Division. Future activities should include an investigation of lower extrusion processing temperatures to optimize the fabrication of high quality iron-aluminide clad tubing.

SURFACE MODIFICATION FOR CORROSION RESISTANCE
K. Natesan Jun. 1993 12 p Presented at the Workshop on Materials for Coal Gasification Power Plant, Petten, Netherlands, 14-16 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE93-017419; ANL/ET/CP-80044; CONF-9306246-1) Avail: CASI HC A03

The raw gas environments that arise from coal gasification have chemical compositions that are low in pO2 and moderate-to-high in pS2. Metallic materials for service in such an environment undergo predominantly sulfidation attack at temperatures of 400 to 700 C. Modification of alloy compositions in bulk can alter the scaling processes and lead to improvements in corrosion resistance, but the benefits can only be attained at temperatures much higher than the service temperatures of the components. Modification of surfaces of structural components by several of the coating techniques examined in this study showed substantial benefit in corrosion resistance when tested in simulated coal gasification environments. The paper presents several examples of surface modification and their corrosion performance.

DUCTILE-BRITTLE TRANSITION BEHAVIOR OF TUNGSTEN UNDER SHOCK LOADING CONDITIONS
D. H. Lassila and G. T. Gray, III (Los Alamos National Lab., NM.) Feb. 1993 16 p Presented at the 13th International Plansee Seminar, Triol, Austria, 24-28 May 1993
(Contract W-7405-eng-48)
(DE93-019945; UCRL-JC-112768; CONF-9305141-2) Avail: CASI HC A03/MF A01

In an effort to characterize the ductile-brittle transition behavior of warm forged tungsten under shock loading conditions, we have performed shock/soft-recovery experiments at 22 and 4000 C. Results at 22 C indicate that shock (19 GPa) induced strains appear to be accommodated by fracture processes, i.e. there were no indications of shock induced plastic deformation, and the test sample was reduced to rubble. At 400 C, the test sample was recovered intact and the shock induced plasticity caused deformation banding and an increase in the dislocation density of the material. For reasons that are unclear, almost no change in the post shock mechanical behavior was observed, despite the significant changes in the microstructure. The results of these experiments demonstrate the principal of a ductile-brittle transition behavior of tungsten under uniaxial shock loading conditions and indicate that explosively driven deformation of tungsten of this material will result in pulverization due to shock loading.

AN ASSESSMENT OF THE COST OF MICROWAVE SINTERING CERAMIC TILES FOR ARMOR APPLICATIONS
S. Das and T. R. Curlee Sep. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE94-000978; ORNL/TM-12423) Avail: CASI HC A03 (US Sales Only)

The sintering component of a process cost model was used to estimate the cost of microwave sintering of alumina and Si carbide tiles. While the process cost model focuses only on cost of the sintering step, preliminary estimates of total cost of a microwave-sintered tile are also provided, assuming that costs of pre- and post-sintering steps will not be altered by adoption of microwave sintering. Base-case cost of microwave sintering alumina tiles is estimated to be $14.98 and $18.17/part for 2.45 and 28 GHz microwave power sources. Cost of microwave sintering is greater than 3 times the cost of conventional sintering, but microwave sintering is not expected to drastically increase the cost of ceramic tiles; the increase factor is only 1.3 times. For Si carbide tiles, the base-case cost of microwave sintering is lower than that of conventional sintering ($39.11 and $41.66/part for 2.45 and 28 GHz sources vs $106.14/part for conventional sintering). Labor is one of the largest sintering cost components in the case of alumina tiles, while for Si carbide tiles, material is the largest sintering cost component. Sensitivity analysis indicate that costs are particularly sensitive to changes in quantity of microwave energy required (kWh/lb) during sintering.

FUNDAMENTAL STUDIES OF STRESS DISTRIBUTIONS AND STRESS RELAXATION IN OXIDE SCALES ON HIGH TEMPERATURE ALLOYS
D. A. Shores, J. H. Stout, and W. W. Gerberich Jun. 1993 45 p
(Contract DE-FG02-88ER-45337)
(DE94-001444; DOE/ER-45337/T5) Avail: CASI HC A03/MF A01

This report summarizes a three-year study of stresses arising in the oxide scale and underlying metal during high temperature oxidation and of scale cracking. In-situ XRD was developed to measure strains during oxidation over 1000 C on pure metals. Acoustic emission was used to observe scale fracture during isothermal oxidation and cooling, and statistical analysis was used to infer mechanical aspects of cracking. A microscratch technique was used to measure the fracture toughness of scale/metal

interface. A theoretical model was evaluated for the development and relaxation of stresses in scale and metal substrate during oxidation. DOE

MOLECULAR DYNAMICS MODELING OF THE MECHANICAL BEHAVIOR OF METALLIC MULTILAYERS
J. Belak and D. B. Boercker Jul. 1993 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993 Revised
(Contract W-7405-eng-48)
(DE93-019947; UCRL-JC-112347-Rev-1; CONF-930405-38-Rev-1) Avail: CASI HC A02/MF A01

Constant-stress molecular dynamics simulations are used to study the mechanical properties of equal concentration Cu-Ni (111) metallic multilayers of repeat lengths 0.4-5.0 nm. Uniaxial stress is applied along the close-packed 110 and perpendicular to the close-packed 112 directions within the (111) plane. The observed elastic modulus does not display a super-modulus effect as observed in experimental bulge tests for the biaxial modulus. However, both the average interlayer spacing and the out-of-plane Poisson ratio display anomalous effects for multilayer repeat lengths below about two nanometers. DOE

NI3AI ALUMINIDE ALLOYS
C. T. Liu 1993 13 p Presented at the International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000493; CONF-930997-6) Avail: CASI HC A03/MF A01

This paper provides a brief review of the recent progress in research and development of Ni3Al and its alloys. Emphasis has been placed on understanding low ductility and brittle fracture of Ni3Al alloys at ambient and elevated temperatures. Recent studies have resulted in identifying both intrinsic and extrinsic factors governing the fracture behavior of Ni3Al alloys. Parallel efforts on alloy design using physical metallurgy principles have led to properties for structural use. Industrial interest in these alloys is high, and examples of industrial involvement in processing and utilization of these alloys are briefly mentioned. DOE

SULFUR-BONDED THIOPHENES IN ORGANOMETALLIC RHENIUM COMPLEXES AND ADSORPTION OF ISOCYANIDES ON GOLD Ph.D. Thesis
M. J. Robertson Aug. 1993 119 p
(Contract W-7405-eng-82)
(DE93-041126; IS-T-1645) Avail: CASI HC A06/MF A02

This dissertation contains results of research conducted in two different areas: (1) organometallic synthesis and reactivity, and (2) organometallic surface chemistry. In the synthesis and reactivity studies, sulfur coordination of thiophene and benzo(b)thiophene to the metal center in organometallic rhenium complexes is examined. In the surface chemistry studies, diffuse reflectance infrared Fourier transform spectroscopy (DRIFTS) is used to analyze the adsorption of several isocyanides on the surface of gold powder. Results are compared and contrasted to known organometallic chemistry. DOE

THE EFFECT OF MICROSTRUCTURAL EVOLUTION ON SUPERPLASTICITY IN NI3SI(V, Mo)
Susan L. Stoner and Amiya K. Mukherjee (California Univ., Davis.) Oct. 1992 14 p Presented at the Advances in Superplasticity and Superplastic Forming, Chicago, IL, 1-5 Nov. 1992
(Contract W-7405-eng-48)
(DE93-041320; UCRL-JC-112108; CONF-9211268-1) Avail: CASI HC A03/MF A01

To further the understanding of superplasticity in intermetallics, this paper presents results of experimental investigations on an intermetallic alloy based on nickel silicide. Specifically, the evolution of the microstructure and its influence on superplastic performance is discussed. In the duplex microstructure, one phase showed grain growth, and the other, grain refinement. Cavitation occurred at interphase boundaries and final failure was by interlinkage of these cavities. Annealing the material improved the homogeneity of the microstructure. The annealed material showed improved strain rate sensitivity values and enhanced superplasticity. Microstructural features and ductility were also influenced by changing the orientation of the tensile axis. Though a transverse orientation showed more cavitation than longitudinal, it yielded greater elongation. An increased resistance to cavity coalescence in the transverse direction played a role in the enhanced ductility. DOE

OBSERVATION OF X RAY ABSORPTION MAGNETIC CIRCULAR DICHROISM IN WELL-CHARACTERIZED IRON-COBALT-PLATINUM MULTILAYERS
A. F. Jankowski, G. D. Waddill, and J. G. Tobin Apr. 1993 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-000303; UCRL-JC-113778; CONF-930405-42) Avail: CASI HC A02/MF A01

Magnetic circular dichroism in the Fe 2p x-ray absorption is observed in multilayers of(Fe9.5(Angstrom)/Pt9.5(Angstrom))(sub 92). The magnetization and helicity are both in the plane of this multilayer which is prepared by magnetron sputter deposition. This sample is part of a study to examine magnetization in the ternary multilayer system of FeCo/Pt. Lattice and layer pair spacings are measured using x-ray scattering. The atomic concentration profiles of the multilayer films are characterized using Auger electron spectroscopy coupled with depth profiling. Conventional and high resolution transmission electron microscopy are used to examine the thin film, growth morphology, and atomic structure. DOE

EFFECT OF POWDER CHARACTERISTICS ON GAS-PRESSURE SINTERING OF Si3N4 WITH RARE EARTH ADDITIVES
T. N. Tiegs, S. D. Nunn, C. A. Walls, D. Barker, C. Davisson, and P. J. Jones 1993 4 p Presented at the International Union of Materials Research Societies on Advanced Materials, Tokyo, Japan, 31 Aug. - 4 Sep. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000330; CONF-9308122-8) Avail: CASI HC A01/MF A01

Several Si3N4 powders, synthesized by various methods and having different surface areas, oxygen contents and impurity levels, were examined. During early stage densification, all powders showed similar shrinkage with the diimide ederived powder exhibiting delayed (alpha)/(beta) transformation compared to the other powders. The diimide and gas-phase derived powders achieved the highest final densities. Improved densification was observed by increasing the oxygen content and this also resulted in high toughness for some materials with rare earth apatite additives. However, the increased oxygen resulted in reduced high temperature strength. Fracture toughnesses (K(sub Ic)) up to 10 MPa sq. root of m were obtained for some compositions. DOE

ALLOYING EFFECTS ON MECHANICAL AND METALLURGICAL PROPERTIES OF NiAl
C. T. Liu, J. A. Horton, E. H. Lee, and E. P. George Jun. 1993 31 p
(Contract DE-AC05-84OR-21400)
(DE93-040814; ORNL/TM-12200) Avail: CASI HC A03/MF A01

Alloying effects were investigated in near-stoichiometric NiAl for improving its mechanical and metallurgical properties. Ternary additions of 19 elements at levels up to 10 at. % were added to NiAl; among them, molybdenum is found to be most effective in improving the room-temperature ductility and high-temperature strength. Alloying with 1.0 +/- 0.6% molybdenum almost doubles the room-temperature tensile ductility of NiAl and triples its yield strength at 1000 C. The creep properties of molybdenum-modified NiAl alloys can be dramatically improved by alloying with up to 1% of niobium or tantalum. Because of the low solubilities of molybdenum and niobium in NiAl, the beneficial effects mainly come from precipitation hardening. Fine and coarse precipitates are revealed by both transmission electron microscopy (TEM) and electron microprobe analyses. Molybdenum-containing alloys possess excellent oxidation resistance and can be fabricated into rod stock by hot extrusion at 900 to 1050 C. This study of alloying effects provides a critical input for the alloy design of ductile and strong NiAl aluminide alloys for high-temperature structural applications. DOE

EVALUATION OF NON-CHROMIUM-CONTAINING DEOXIDIZERS FOR ALUMINUM
T. L. Kempf and C. J. Stimetz Aug. 1993 31 p
(Contract DE-AC04-76DP-00613)
(DE94-001377; KCP-613-5255) Avail: CASI HC A03/MF A01

Environmental and regulatory pressures make it necessary to eliminate the use of hexavalent chromium wherever possible. This report discusses the evaluation of non-chromium deoxidizers as replacements for a hexavalent chromium dioxidizer. The current deoxidizer is used as a deoxidizer for anodizing aluminum and chromate conversion coating as well as a cleaner prior to welding. Performance of replacement deoxidizers was evaluated through salt spray testing, surface analysis, optical metallography, radiography and dye-penetrant analysis of welds, and a production simulation. STRENGTHENING AND TOUGHENING IN REFRACTORY METAL ALLOYS
J. Wadsworth, T. G. Nieh, and J. Wittenauer (Lockheed Missiles and Space Co., Palo Alto, CA.) Mar. 1993 16 p Presented at the Conference on Critical Issues in the Development of High Temperature Structural Materials, Kona, HI, 7-12 Mar. 1993
(Contract W-7405-eng-48)
(DE93-019942; UCRL-JC-113795; CONF-930317-2) Avail: CASI HC A03/MF A01

Development and application of refractory metal alloys for high temperature aerospace structures is reviewed. The use of refractory metals is often limited by poor room temperature properties, inadequate oxidation resistance at elevated temperatures, or difficulties associated with joining, welding, or forming. Materials selection criteria for high temperature structures are reviewed with an emphasis placed upon the distinctions between refractory metals and competing high temperature materials -- including carbon, ceramics, and intermetallics. Each class of materials has inherent limitations which govern application. In some cases, materials limitations are being solved through the use of engineered materials hybrids such as ceramic-coated refractory metals or ceramics roughened with a ductile refractory metal phase. For many applications, use of ceramics and intermetallics is limited by their technological immaturity. For example, current understanding and application of molybdenum-based materials is based upon nearly 40 years of application experience in high temperature structures. As an example of a materials development and qualification program, a brief synopsis of molybdenum alloy development is presented. Topics surveyed include recent advances in the understanding of the role of oxygen on the room temperature brittle behavior problem in molybdenum alloys. DOE

MICROTEXTURAL CHARACTERIZATION OF ANNEALED AND DEFORMED COPPER
S. I. Wright and F. Heidelbach 1993 6 p Presented at the International Conference on Textures of Materials, Clausthal, Germany, 20-24 Sep. 1993
(Contract W-7405-eng-36)
(DE93-040144; LA-UR-93-3115; CONF-9309231-1) Avail: CASI HC A02/MF A01

Even though deformation produces material with preferred orientation it appears to randomize the grain boundary texture in copper. It appears that as dislocations move through the material the resulting lattice rotations serve to break down the twin structure in a stochastic manner. An effort was made to use the automatic BEKP data to search for dislocation cell wall structures. However, no evidence was found for such structure. This may be due, in part, to the resolution of the backscatter electron Kikuchidi diffraction pattern technique. Diffraction occurs from an area with mean diameter of approximately 0.5 mu m. DOE

SHOCK TEMPERATURE MEASUREMENTS OF IRON TO 350 GPa
C. S. Yoo, N. C. Holmes, M. Ross, and E. See Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-001058; UCRL-JC-113406; CONF-930676-54) Avail: CASI HC A02/MF A01

Shock temperatures of iron have been measured to 350 GPa, using high quality well-characterized iron films deposited on diamond substrates. The authors have found an inflection in the (P,T)-iron Hugoniot between 250 GPa and 300 GPa, indicating iron melting at 6,350 K and 6,720 K, respectively. An extrapolation yields the iron melting temperature of 6,870 (+/- 500) K at 330 GPa, the pressure of the Earth inner core-outer core boundary. In this paper, they present this new iron melting data together with a brief description of the experimental method to measure the shock temperatures of iron. DOE

INTERFACE SCIENCE OF CONTROLLED METAL/METAL AND METAL/CERAMIC INTERFACES PREPARED USING ULTRAHIGH VACUUM DIFFUSION BONDING
W. E. King, G. H. Campbell, A. W. Coombs, G. W. Johnson, B. E. Kelly, T. C. Reitz, S. L. Stoner, W. L. Wien, and D. M. Wilson Apr. 1993 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-001066; UCRL-JC-113779; CONF-930405-46) Avail: CASI HC A02/MF A01

We have designed, constructed, and are operating a capability for production of controlled homophase and heterophase interfaces: an ultrahigh vacuum diffusion bonding machine. This machine is based on a previous design which is operating at the Max Planck Institut fuer Metallforschung, Institut fuer Werkstoffwissenschaft, Stuttgart, FRG. In this method, flat-polished single or polycrystals of materials with controlled surfaced topography can be heat treated up to 1500 C in ultrahigh vacuum. Surfaces of annealed samples can be sputter cleaned and characterized prior to bonding. Samples can then be precisely aligned crystallographically to obtain desired grain boundary misorientations. Material couples can then be bonded at temperatures up to 1500 C and pressures up to 10 MPa. Results are presented from initial work on Mo grain boundaries and Cu/Al2O3. DOE

SURFACE MODIFICATION OF Ti3Al FOR IMPROVED OXIDATION RESISTANCE
R. U. Vaidya, A. K. Zurek, R. Castro, Y. W. Sin (Michigan State Univ., East Lansing.), and K. N. Subramanian (Michigan State Univ., East Lansing.) 1993 26 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials in Conjunction With Materials Week and the Materials Applications and Services Exposition, Pittsburgh, PA, 17-21 Oct. 1993
(Contract W-7405-eng-36)
(DE93-018297; LA-UR-93-2686; CONF-931009-2) Avail: CASI HC A03/MF A01

Ti3Al has very attractive properties such as low density and high temperature mechanical strength for elevated temperature structural applications. Its major drawback however, is poor oxidation resistance at temperatures above 600 C. Potential use of Ti3Al in high temperature applications depends on its protection from excessive oxidation. To this effect, Al2O3 and Al3Ti were selected as coating materials chemically compatible with Ti3Al. Al2O3 acts as a protective layer on the surface of Ti3Al and is impervious to oxygen diffusion. Al3Ti is resistant to high temperatures and also protects the Ti3Al substrate by forming an oxide layer consisting primarily of Al2O3. In this study, Al2O3 was plasma sprayed onto the surface of Ti3Al, while the Al3Ti was applied by laser melting. Effectiveness of the coatings were investigated after 10 hours of cyclic oxidation. DOE

MICROSTRUCTURAL EVOLUTION OF NEUTRON-IRRADIATED Fe-Cr-Ni TERNARY ALLOYS AT HIGH HELIUM GENERATION RATES
N. Sekimura (Tokyo Univ., Japan.) and F. A. Garner Jul. 1993 21 p Presented at the 3rd Conference on Evolution of Microstructure in Metals During Irradiation, Chalk River, Canada, 29 Sep. - 2 Oct. 1992
(Contract DE-AC06-76RL-01830)
(DE93-018786; PNL-SA-20214; CONF-920970-9) Avail: CASI HC A03/MF A01

A series of Fe-Cr-Ni ternary alloys were irradiated to 12-14 dpa in the Oak Ridge Research Reactor (ORR). In this experiment, most of helium atoms were produced by the (58)Ni(n, gamma)(59)Ni(n, alpha)(56)Fe sequential reaction, and, therefore, the helium generation rate was almost proportional to the nickel content, ranging from 27 to 58 appm He/dpa in 20 to 45 wt.% Ni alloys. Irradiation temperatures were 330, 400, 500 and 600 C, and the specimen variables were the nickel level, the chromium level and cold working. The high levels helium, combined with details of the temperature history, were found to have dominated microstructural development, sometimes overwhelming and even reversing the action of a given material variable. Microscopy examination showed that there was an unprecedented refinement of cavity microstructure at all temperatures, which accounts for the substantial alterations in both swelling and mechanical properties observed in earlier studies. DOE

THEORETICAL STUDIES OF STRUCTURAL PHASE TRANSITIONS IN ACTINIDE METALS
J. M. Wills, A. M. Boring, O. Eriksson (Uppsala Univ., Sweden.), and P. Soederlind (Uppsala Univ., Sweden.) 1993 14 p Presented at the Actinides 1993, Santa Fe, NM, 19-24 Sep. 1993
(Contract W-7405-eng-36)
(DE94-000796; LA-UR-93-3249; CONF-930905-3) Avail: CASI HC A03/MF A01

Accurate full-potential, relativistic, total energy electronic structure calculations have been carried out over a range of volumes for selected rare-earth and actinide elements in crystal structures experimentally observed in these elements. Correct zero temperature crystal structures are obtained, and calculated equilibrium properties are in reasonable agreement with experiment. Results of these calculations suggest that the unusual equilibrium crystal structures occurring in the light actinides are characteristic of narrow band metals in general and that the light actinides will exhibit structural phase transitions to high symmetry structures under compression. A balance between one-electron bandwidths and band fillings and the electrostatic energy of the crystal lattice produces a tendency toward high-symmetry structures at broad bandwidths and low-symmetry structures at narrow bandwidths. Allowing for expansion as well as contraction, simple metals, transition metals and actinides can be 'stabilized' in low- and high-symmetry crystal structures. DOE

TRANSMISSION ELECTRON MICROSCOPY STUDY OF THICK COPPER-304 STAINLESS STEEL MULTILAYERS
M. A. Wall, T. W. Barbee, Jr., and T. Weihs Jun. 1993 6 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-001045; UCRL-JC-112054; CONF-930405-45) Avail: CASI HC A02/MF A01

Thick (10 to 25 micron), free-standing, equal layer thickness, Copper(Cu)-304 Stainless Steel(SS) multilayer foils, having periods of 1 to 100 nm, synthesized by magnetron sputter deposition, were examined by plan view and cross-sectional transmission electron microscopy. Multilayer growth morphology, individual layer structure and crystallographic phase orientation relationships were characterized in this study. Electron Energy Loss filtered imaging of a 20 nm period multilayer cross-section was also performed and showed that nickel had diffused into the Cu layers from the SS during synthesis. X-ray powder diffraction scans were performed and analyzed. A pure deposit of 304SS was synthesized and had a metastable BCC structure. Multilayer samples having periods of 20 nm were found to have a coherent layered Cu(FCC)SS(FCC) structure. At larger periods (50 and 100 nm) a bimodal Cu(FCC)-SS(FCC and BCC) structure was formed. These observations show that the 304SS will grow with a metastable BCC structure when sputter deposited. When layered with Cu(FCC) the 304SS has its equilibrium FCC structure at layer thicknesses up to 10nm as a result of epitaxy with the copper. At larger SS layer thicknesses, the SS appears to locally transform to the metastable BCC structure during synthesis, refining the grain structure of the depositing SS layer and the subsequent Cu layer. This transformation significantly increases the strength of the larger period multilayer. DOE

FIRST-PRINCIPLES PRESSURE-TEMPERATURE PHASE DIAGRAMS IN METALS
J. A. Moriarty Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE94-001056; UCRL-JC-113300; CONF-930676-55) Avail: CASI HC A02/MF A01

Using interatomic potentials derived from first-principles generalized pseudopotential theory, finite-temperature phase transitions in both simple and transition metals can be studied through a combination of analytic

statistical methods and molecular-dynamics simulation. In the prototype simple metal Mg, where volume and pair forces adequately describe the energetics, a complete and accurate phase diagram has thereby been obtained to 60 GPa. A rapidly temperature-dependent hcp-bcc phase line is predicted which ends in a triple point on the melting curve near 4 GPa. In central transition metals such as Mo or Fe, on the other hand, the energetics are complicated by d-state interactions which give rise to both many-body angular forces and enhanced electron-thermal contributions. We have made a detailed study of these phenomena and their impact on melting in the prototype case of Mo and a full melting curve to 2 Mbar has been obtained. In the case of Fe, we are examining the high-pressure phase diagram and the question of whether or not there exists a high-pressure, high-temperature solid bcc phase, as has been speculated. To date, we have shown that the bcc structure is both thermodynamically and mechanically unstable at high pressure and zero temperature, with a large and increasing bcc-hcp energy difference under compression. DOE

N94-22402# Lawrence Livermore National Lab., CA.
USING THE RULE OF MIXTURES TO EXAMINE THE HARDNESS OF Cu/Cu-Zr MULTILAYERS
T. P. Weihs, T. W. Barbee, Jr., and M. A. Wall Jun. 1993 8 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract W-7405-eng-48)
(DE94-001068; UCRL-JC-114157; CONF-930405-44) Avail: CASI HC A02/MF A01

Cu/Cu-Zr multilayer foils were fabricated and indented to determine the degree to which multilayer hardness is enhanced by increasing the volume fraction of the harder phase. Using sputter deposition and thermal processing a series of foils was fabricated in which the thicknesses of the Cu layers remained fixed while the thicknesses of the alternate Cu-Zr layers varied. These samples were then indented both parallel and normal to their layering. In general hardness increased as the volume fraction of the harder Cu-Zr phase rose. When the films were loaded parallel to their layering, the measured hardnesses were higher and the dependencies on volume fraction of the Cu-Zr phase were stronger than when the films were loaded nominal to their layering. These results agree with predictions based on isostress and isostrain theories. The relations between hardness and volume fraction are used to compare the hardnesses of the Cu-Zr phases: amorphous Cu-Zr, Cu51Zr14 and Cu9Zr2, and to show that the hardness of the textured, as-deposited Zr layers is highly anisotropic. DOE

MINIATURIZED DISK-BEND TESTING, NANO-INDENTATION, AND THE MICROSTRUCTURE OF ION-IRRADIATED TITANIUM ALUMINIDES
N. L. Petouhoff (California Univ., Los Angeles.), A. J. Ardell (California Univ., Los Angeles.), W. C. Oliver, and B. N. Lucas 1993 10 p Presented at the International Symposium on Structural Intermetallics, Champion, PA, 26-30 Sep. 1993
(Contracts DE-AC05-84OR-21400; DE-FG03-86ER-45264; DE-AC05-76OR-00033)
(DE93-040600; CONF-930997-5) Avail: CASI HC A02/MF A01

Effect of ion irradiation on microstructures and mechanical properties of Ti-52Al (TiAl) and Ti-26Al (Ti3Al) were investigated. The alloys were irradiated with 2 MeV protons and Ar(+) ions at low temperatures (-175 to -135C) to max fluences of 4.5 x 10(exp 15) Ar(+)/cm(exp 2) and 2 x 10(exp 17) H(+)/cm(exp 2). Yield strengths of unirradiated TiAl and the fracture strength of unirradiated Ti3Al were 367 +/- 33 MPa and 536 +/- 30 MPa, respectively, in excellent agreement with published data. Yield strength of TiAl and fracture strength of Ti3Al increased as a result of irradiation. Strengths of both alloys were lowest for the samples irradiated to the highest Ar(+)-ion dose, but otherwise there was no correlation of strength with dose. The nanohardness of irradiated specimens generally increased with dose, but influence of dose on Young's modulus was erratic. Plate-shaped defects vacancy in character, and helical dislocations were observed in irradiated TiAl by TEM. The Ar(+)-ion irradiation-induced microstructure of Ti3Al contained defects producing mottled contrast at 1 dpa and black-spot contrast at 5 dpa. Irradiation-induced loss of long-range order was also observed in both alloys. Influence of these microstructural variables on mechanical behavior is discussed. DOE

STRENGTH, ULTRASONIC AND METALLURGICAL EVALUATION OF DIFFUSION BONDS
G. C. Ojard, O. Buck, and D. K. Rehbein 1993 8 p Presented at the Annual Winter Meeting of the ASME, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract W-7405-eng-82)
(DE94-000665; IS-M-762; CONF-931121-24) Avail: CASI HC A02/MF A01

Diffusion bonding allows similar and dissimilar materials to be bonded together in near net shape. However, differentiation of almost perfect diffusion bonds, with little variation in their acoustic response, is of critical importance since relatively significant changes in bond strength may be a consequence. The challenge is to find ultrasonic techniques sensitive enough to detect small imperfections at interface. Diffusion bonds have been produced that show only a slight variation in a single frequency reflection measurement. The total energy, reflected from the bond line, can differentiate these diffusion bonds. This evaluation is based on Parseval's theorem which states that energy in time domain is proportional to energy in the frequency domain. This measurement takes advantage of presence of voids in the diffusion bonds as well as of the interdiffusion zone. Cu and Ni were chosen as the materials to be bonded due to the case of microstructural control. Diffusion bonds fabricated of Ti-6Al-4V are also discussed. DOE

High damping steel-laminated elastomeric seismic isolation bearings are one of the preferred devices for isolating large buildings and structures. In the U.S., the current reference design for the Advanced Liquid Metal Reactor (ALMR) uses laminated bearings for seismic isolation. These bearings are constructed from alternating layers of high damping rubber and steel plates. They are typically designed for shear strains between 50 and 100% and are expected to sustain two to three times these levels for beyond design basis loading conditions. Elastomeric bearings are currently designed to provide a system frequency between 0.4 and 0.8 Hz and expected to operate between -20 and 40 C. To assure proper performance of isolation bearings, it is necessary to characterize the elastomer's response

under expected variations of frequency and temperature. The dynamic response of the elastomer must be characterized within the frequency range that spans the bearing acceptance test frequency, which may be as low as 0.005 Hz, and the design frequency. Similarly, the variation in mechanical characteristics of the elastomer must be determined over the design temperature range. This paper reports on the capabilities of a testing facility at ANL for testing candidate elastomers, the variation with frequency and temperature of the stiffness and damping of one candidate elastomer, and the effect of these variations on bearing acceptance testing criteria and on the choice of bearing design values for stiffness and damping. SUBSTRATE RECOVERY OF Mo-Si MULTILAYER COATED OPTICS
D. G. Stearns and S. L. Baker Jun. 1993 8 p Presented at the Optical Society of America Topical Meeting on Soft X Ray Projection Lithography, Monterey, CA, 10-12 May 1993
(Contract W-7405-eng-48)
(DE93-019610; UCRL-JC-114087; CONF-9305159-7) Avail: CASI HC A02/MF A01

Imaging optics in a soft x-ray projection lithography (SXPL) system must meet stringent requirements to achieve high throughput and diffraction limited performance. Errors in the surface figure must be kept to less than approximately 1 nm and the rms surface roughness must be less than 0.1 nm. The ML coatings must provide high reflectivity (greater than 60%) at wavelengths in the vicinity of 13 nm. The reflectivity bandpasses of the optics must be aligned within 0.05 nm. Each coating must be uniform across the surface of the optic to within 0.5%. These specifications challenge the limits of the current capabilities in optics fabrication and ML deposition. Consequently a set of qualified SXPL imaging optics is expected to be expensive, costing in the range of $100,000-$250,000. If the lifetime of the imaging optics is short, the replacement cost could significantly impact the economic competitiveness of the technology. The most likely failure modes for the imaging optics are mechanisms that degrade the ML coatings, but which leave the substrates intact. A potentially low cost solution for salvaging the imaging optics could be to strip the damaged ML coating to recover the substrate and then deposit a new coating. In this paper the authors report on the use of reactive ion etching (RIE) to remove Mo-Si ML coatings from precision optical substrates. The goal of this work is to characterize the etching process both in the ML film and at the substrate, and to determine the effects of the etching on the surface figure and finish of the substrate. HYDRODYNAMIC COMPRESSIBILITY OF HIGH-STRENGTH CERAMICS
D. E. Grady 1993 11 p Presented at the Army Symposium on Solid Mechanics, Plymouth, MA, 17-19 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019424; SAND-93-1640C; CONF-9308133-3) Avail: CASI HC A03/MF A01

In this study the author has developed the techniques to investigate the hydrodynamic response of high-strength ceramics by mixing these powders with copper powder, preparing compacts, and performing shock compression tests on these mixtures. Hydrodynamic properties of silicon carbide, titanium diboride, and boron carbide to 30 GPa are examined by this method, and hydrodynamic compression data for these ceramics are presented. It is concluded, however, that the measurement method is sensitive to sample preparation and uncertainties in shock wave measurements. Application of the experimental technique is difficult and further efforts are needed. DOE

EXPANDED POLYSTYRENE PROTECTIVE BARRICADE FULL-SCALE FIRE EXPOSURE TEST Final Report
J. H. Storm, B. R. Dees, and M. J. Wilson Nov. 1992 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F08635-88-C-0067)
(AD-A271450; AFESC/ESL-TR-92-53) Avail: CASI HC A03

This test program evaluated the burning characteristics of expanded polystyrene foam used as a munitions barricade in underground storage facilities. In accordance with nationally-accepted standards, a crib fire burning 30 pounds of wood was used as the ignition source. Standard sheet rock was evaluated as a protective material for the polystyrene barricades. Additionally, the two potential ignition sources present within munitions storage bays, an electrically overloaded light fixture and a 4 ounce paint spill, were evaluated for their ability to ignite the test polystyrene cell. While the sheet rock did protect the polystyrene from the fire and extend the time to failure, test results show that a large fire will melt the polystyrene material releasing the sand and extinguishing fire before a dangerous temperature is reached at the weapons location or serious damage is done. Therefore, a polystyrene barricade retrofit with a protective covering does not appear to be warranted. DTIC

AB INITIO POTENTIAL ENERGY SURFACE FOR THE H + OCS REACTION Final Report, Feb. 1992 - 1993
Betsy M. Rice, Harry E. Cartland, and Cary F. Chabalowski Oct. 1993 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-61102-AH-43)
(AD-A270577; ARL-TR-231) Avail: CASI HC A03

An ab initio MP4 study has been made of the potential energy surface of the H + OCS reaction, and saddle points leading to formation of OH + CS or SH + CO were found. Stationary points were located using the 6-31G** basis set at the ROHF and UMP2 levels of theory, with energy refinements at the MP4(SDTQ) level. Six minima corresponding to conformers of the HOCS system were calculated and transition states leading into and out of these minima were determined. This theoretical study, in conjunction with the recent experimental results of Boehmer, Mikhaylichenko, and Wittig, provides a mechanistic overview of the reactions of the H + OCS system. The results substantiate earlier experimental hypotheses of the existence of stable, four-body reaction intermediates, as well as tight four-body transition states leading to products. Our results also show that these transition states have nonlinear structures, contrary to assumptions made

in earlier experimental work. Our calculations provide the first set of structural data that detail the reaction mechanisms for H + OCS going to SH + CO or OH + CS. In addition, the feature of this potential energy surface suggest explanations for observed nonstatistical behavior in product energy distributions of the SH + CO channel, and the statistical behavior observed in the product energy distributions of the OH + CS channel. SOLDER TECHNOLOGY IN THE MANUFACTURING OF ELECTRONIC PRODUCTS
P. T. Vianco 1993 72 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018842; SAND-93-1604C; CONF-930616-23) Avail: CASI HC A04/MF A01

The electronics industry has relied heavily upon the use of soldering for both package construction and circuit assembly. The solder attachment of devices onto printed circuit boards and ceramic microcircuits has supported the high volume manufacturing processes responsible for low cost, high quality consumer products and military hardware. Defects incurred during the manufacturing process are minimized by the proper selection of solder alloys, substrate materials, and process parameters. Prototyping efforts are then used to evaluate the manufacturability of the chosen material systems. Once manufacturing feasibility has been established, service reliability of the final product is evaluated through accelerated testing procedures. DOE

OUTGASSING RATE OF REEMAY SPUNBONDED POLYESTER AND DUPONT DOUBLE ALUMINIZED MYLAR
R. J. Todd, D. Pate, and K. M. Welch Aug. 1993 8 p
(Contract DE-AC02-76CH-00016)
(DE93-040015; BNL-49345) Avail: CASI HC A02/MF A01

This paper presents the outgassing rates of two commercially available multi-layer insulation (MLI) materials commonly used in cryogenic applications. Both Reemay Spunbonded Polyester and DuPont Double Aluminized Mylar (DAM) were studied for outgassing species and respective rates, and the total amount of outgassed material. Measurements were made using a Fixed Aperture Technique. A sample was pumped on through an aperture of known size with a turbomolecular pump. Pressure vs. time was plotted for both Reemay and DAM, as well as the baseline system, and data conveniently extrapolated to approximately 1,000 hrs. A quadrupole residual gas analyzer was used to measure the outgassing species. DOE

THERMAL BEHAVIOR OF NATURAL ZEOLITES
D. L. Bish 1993 22 p Presented at the Zeolite 1993: 4th International Conference on the Occurrence, Properties, and Utilization of Natural Zeolites, Boise, ID, 20-28 Jun. 1993
(Contract W-7405-eng-36)
(DE93-040091; LA-UR-93-2881; CONF-9306100-5) Avail: CASI HC A03/MF A01

Thermal behavior of natural zeolites impacts their application and identification and varies significantly from zeolite to zeolite. Zeolites evolve H2O upon heating, but recent data show that distinct 'types' of water (e.g., loosely bound or tightly bound zeolitic water) do not exist. Rather water is bound primarily to extra-framework cations with a continuum of energies, giving rise to pseudocontinuous loss of water accompanied by a dynamic interaction between remaining H2O molecules and extra-framework cations. These interactions in the channels of zeolites give rise to dehydration dependent on the extra-framework cation, in addition to temperature and water vapor pressure. The dehydration reaction and the extra-framework cation also affect the thermal expansion/contraction. Most zeolites undergo dehydration-induced contractions that may be anisotropic, although minor thermal expansion can be seen with some zeolites. Such contractions can be partially or completely irreversible if they involve modifications of the tetrahedral framework and/or if rehydration is sluggish. Thermally induced structural modifications are also driven initially by dehydration and the concomitant contraction and migration of extra-framework cations. Contraction is accommodated by rotations of structural units and tetrahedral cation-oxygen linkages may break. Thermal reactions that involve breaking of tetrahedral cation-oxygen bonds markedly irreversible and may be kinetically limited, producing large differences between short- and long-term heating. DOE

CHAIN PROPAGATION/STEP PROPAGATION POLYMERIZATION CHEMISTRY. THE PREPARATION OF SOLVENT RESISTANT WELL PHASE-SEPARATED THERMOPLASTIC ELASTOMERS Final Report, 16 Aug. 1989 - 15 Aug. 1993
Ken B. Wagener 30 Sep. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-89-K-0103)
(AD-A271128; ARO-26441.5-CH) Avail: CASI HC A03

The essence of the research consists of synthesizing unsaturated, chlorofunctionalized carbosilanes or carbosiloxanes as a backbone polymer, and recent work with model compounds suggests that these syntheses will be successful. These chlorofunctionalized backbone polymers will be converted into either solvent resistant elastomers or high T(sub g) materials via nucleophilic grafting reactions, chemistry which is reminiscent of the work done with polyphosphazene backbones. Thus, the goals of this research are as follows: to synthesize a variety of unsaturated polycarbosilanes and carbosiloxanes functionalized with the silicon-chlorine bond, to graft low and high molecular weight sidechains on these backbones to tailor their physical behavior to specific needs, and, to demonstrate that these polymers can be recycled via depolymerization. As is normally the case, full structural characterization work will accompany all phases of this research. A successful effort will lead to the creation of recyclable materials for a variety of applications including lubricants, face masks, high performance engineering plastics, coatings, and self lubrication plastics. The final report summarized the research results. DTIC

POLYMER GELS AS PRECURSORS TO HIGH-PERFORMANCE MATERIALS Final Report, 1 Jun. 1990 - 31 May 1993
J. E. Mark 6 Jul. 1993 9 p
(Contract DAAL03-90-G-0131)
(AD-A270937; ARO-27373.10-MS) Avail: CASI HC A02/MF A01

The three types of materials covered in this investigation were (1) thermoreversible gels of organic polymers (such as polyethylene), (2) non-reversible gels obtained by the hydrolysis of organometallics and used as precursors to inorganic ceramics (silica and titania), and (3) hybrid composites prepared by having siloxane polymers present during the in-situ generation of the ceramic species. The kinetics of the gelation process were determined by measuring the shear moduli of the gels as a function of time for various compositions and catalyst concentrations. Of particular interest was the observed decreases in gelation time with increase in concentration of either catalyst (through increases in reaction rates) or polymer (through increases in the number of high molecular weight species necessary for gelation). Composites obtained by densification of the gels were characterized by NMR imaging, neutron and x-ray scattering, and impact strength measurements. The polymer components in the hybrid organic-inorganic composites was found to greatly increase their impact strengths. DTIC

GROWTH MECHANISMS AND CHARACTERIZATION OF HYDROGENATED AMORPHOUS-SILICON-ALLOY FILMS

A. Gallagher, D. Tanenbaum, A. Laracuente, and E. Molenbroek Aug. 1993 25 p Prepared in cooperation with Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-018202; NREL/TP-411-5749) Avail: CASI HC A03/MF A01

Work performed to better understand the atomic-scale structure of glow-discharge-produced a-Si:H, a Ge:H, and a-Si:Ge:H films; its effect on film quality; and its dependence on deposition discharge conditions are described. Hydrogenated a-Si films are deposited from a silane rf discharge onto atomically flat crystal Si and GaAs substrates. The substrates are then transferred in vacuum to a scanning tunneling microscope, where the atomic-scale surface morphology is measured. The films were deposited at T(sub s) = 30 C and 250 C from a silane rf glow discharge using device-quality deposition conditions of 2.66 Pa (0.5 Torr) silane pressure, 1.7 Angstrom/s deposition rate, and small power/flow; IR absorption, sigma(sub L), and sigma(sub D) indicate high-quality intrinsic films. From the thickness dependence of the surface morphology, it was determined that the films initially conform smoothly to an atomically flat Si or GaAs substrate, but as the thickness increases the roughness steadily increases to approximately 10% of the length of the scanned region. The surface of 100-400 nm thick films is highly inhomogeneous, with steep hills and canyons in some areas and large atomically smooth regions in others. These unexpectedly large surface irregularities indicate severe and often connected void structures in the growing film, as well as relatively limited-range surface diffusion of the incorporating SiH3 radicals. On the other hand, large areas of atomically flat surface were occasionally found, indicating the possibility of growing a homogeneous and compact amorphous film if appropriate growth conditions could be discovered. The use of guanidine salts of organic fatty acids (guanidine soaps) as vehicles and binders for coating substrate surfaces is disclosed. Being completely organic, the guanidine soaps can be burned off leaving no undesirable residue. Of special interest is the use of guanidine 2-ethyl hexanoate as the vehicle and binder for coating problematic surfaces such as in coating alumina fibers with platinum or zirconia. For this application, the guanidine soap is used as a melt. For applications, the guanidine soap may be use in a solution with a variety of solvents, the solution containing chlorometalates or powdered metals, refractories, or ceramics.

NEUTRON-SCATTERING STUDIES OF Yb-BEARING SILICATE GLASSES
A. J. G. Ellison, C. K. Loong, and J. Wagner 1993 14 p Presented at the 20th Rare Earth Research Conference, Monterey, CA, 12-17 Sep. 1993
(Contract W-31-109-eng-38)
(DE93-019768; ANL/MSD/CP-79820; CONF-9309142-1) Avail: CASI HC A03/MF A01

The static and dynamic magnetic responses of the Yb(3+) ions in 2Na2O center dot Yb2O3 center dot 6SiO2 glass and the isochemical crystalline silicate Na3YbSi3O9 are studied by neutron diffraction, inelastic magnetic-scattering, and magnetic susceptibility measurements. The rare earth sites in the glass have an average coordination number of 5.6 +/- 0.5 and give a mean rare earth-oxygen bond length of 2.23 Angstrom; average Si-O and O-O coordination numbers and bond distances are comparable to those in vitreous SiO2. The magnetic excitation spectrum of the Na3YbSi3O9 material is analyzed by a crystal-field model using a method of descending symmetry. The magnetic susceptibility and the excitation spectrum of the Yb glasses can be described by a distribution of ligand-field effects on the Yb(3+) ions that are similar to the nominal crystal field in crystalline Na3YbSi3O9. LATERAL DISTRIBUTION OF LIPIDS IN MEMBRANES AT HIGH PRESSURE Final Report, 1 Jul. 1991 - 30 Jun. 1993
Parkson L. Chong and Istvan P. Sugar 13 Jul. 1993 4 p
(Contract DAAL03-91-G-0228)
(AD-A271183; ARO-28657.3-LS-SAH) Avail: CASI HC A01/MF A01

This research is to study the lateral distribution of 1-palmitoyl-1-(10-pyreny)decanoyl)- sn-glycerol- 3-phosphatidylcholine (Pyr-PC) in dimyristoylphosphatidylcholine (DMPC) bilayer membranes. Fluorescence and statistical mechanics are employed. A series of dips were found in the plot of E/M (the ratio of excimer fluorescence to monomer fluorescence) vs. the mole fraction of Pyr-PC. The results can be interpreted in terms of the extended hexagonal super-lattice model. Based on this model, lipids in the Pyr-PC/DMPC binary mixtures are regularly distributed in the membrane. Pressure data further suggest that the bilayer membrane has more free volume at non-critical concentrations and more free volume when the regular distribution (as compared to the irregular region) reaches a local minimum. The computer simulation work further suggests that the area of regular arrangements have local maxima at the critical mole fractions if the repulsive interaction between Pyr-PC's is strong enough. LIGHT SCATTERING STUDIES OF AN ELECTRORHEOLOGICAL FLUID
J. E. Martin and J. Odinek 1993 17 p Presented at the 2nd International Discussion Meeting on Relaxations in Complex Systems, Alicante, Spain, 28 Jun. - 8 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE93-019419; SAND-93-1844C; CONF-9306224-1) Avail: Issuing Activity (Department of Energy (DOE))

The authors report real-time, two-dimensional light scattering studies of the evolution of structure in an electrorheological fluid in the quiescent state and under shear. They find that when an electric field is applied to the quiescent fluid, particles chain along the electric field lines and cause strong light scattering lobes to appear at a finite scattering wave-vector q orthogonal to the field lines. These lobes then brighten as they move to q=O, indicating the existence of an unstable concentration fluctuation that signifies the segregation of chains into columns. In fact, the observed power law growth kinetics of the characteristic length, as well as the form of the structure factor, are qualitatively similar to two-dimensional spinodal decomposition in a system with a conserved order parameter. When the sample is subjected to shear, the authors find that the scattering pattern approaches a steady state, with lobes that are rotated in the direction of fluid vorticity. The angle of rotation is found to increase as the cube root of the shear rate, in agreement with a theoretical prediction of the steady state structure of fragmenting particle chains. DOE

THE MODIFICATION OF POLYMER SURFACES AND THE FABRICATION OF SUBMICRON-SCALE FUNCTIONALIZED STRUCTURES BY DEEP-UV AND ELECTRON BEAM LITHOGRAPHY Technical Report, Mar. 1992 - Jun. 1993

M. N. Wybourne, J. C. Wu, Ming-Di Yan, Sui X. Cai, and John F. Keana 10 Jun. 1993 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1412)
(AD-A265956; UO-JFWK-MNW-05) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We present a general technique to modify polymer surfaces using N-hydroxysuccinimide (NHS) functionalized perfluorophenyl azides (PFPA's). Thin polystyrene films are spin-coated with a solution containing the NHS PFPA ester and are either UV photolyzed with a dosage of 10 mJ cm(exp -2) or exposed with a 15 kV electron beam with a dosage between 1 and 75 (mu)m cm(exp -2). The NHS active ester groups become covalently attached to the polymer via photogenerated or electron beam generated, highly reactive nitrene intermediates derived form the PFPA. Using this technique we demonstrate that well-defined surface regions can be functionalized with a minimum observable feature size of 0.5 (mu)m and 0.2 (mu)m for UV and electron beam exposure, respectively. Through reaction of the functionalized surfaces with primary amine-containing reagents, we have installed biological molecules on the polymer and have measured the activity of an immobilized enzyme. A method for producing internally coated glass tube preforms for drawing Fiber optic conductors is presented. The internally coated glass tubes are halogen coated, preferably coated with metal fluorides, so that an optical fiber formed will have a halogen core which conveys light having a wavelength of about 2 to 4 microns, which is in the infrared region, with low attenuation. With one aspect of the method, a carrier gas and a halogenated alkoxide are introduced into a glass tube which has an inner wall and which is surrounded by a resonator for producing a plasma from the halogenated alkoxide in the tube. With another aspect of the method, a blend of a carrier gas, an organometallic compound, and a halogen-containing gas are introduced into a glass tube which has an inner wall and which is surrounded by a resonator for producing a plasma. In crystallization measurements of nonisothermal nucleation for Li2O.2SiO2 (LS2) glass, using DTA, the glass sample is scanned at different constant heating rates until it is crystallized. This means that the temperature range where nucleation can occur for the glass is scanned also at different rates which allows the glass to be nucleated for different time prior to crystallization. Consequently, the concentration of nuclei developed in the glass may be different for different heating rates and the DTA peak height which has shown to be sensitive to the number of nuclei present in the sample, is expected to change with heating rate. DTA peak height depends strongly on the overlap between the nucleation rate and growth rate curves, assuming the peak height is directly proportional to the total number of nuclei present in the glass sample under investigation, which, in turn, should be proportional to the volume or weight of the sample. To verify this assumption, DTA measurements were made using a LS2 glass to determine the peak height as a function of the sample weight. Using the DTA peak height technique, a nucleation rate like curve was determined for the BaO.2SiO2 (BS2) glass which showed that the temperature for nucleation ranged from 650 to 750 C for this glass and the temperature for maximum nucleation was approximately 705 C. These values are in excellent agreement with those determined by the conventional technique. There was international collaboration with Japan and Germany on this project. Derived from text

An optimal time-space multi-resolution approach has been designed to carry out large-scale molecular-dynamics (MD) simulations on distributed-memory MIMD (Multiple Instructions Multiple Data) machines. The multi-resolution MD approach was used to investigate structural correlations in porous silica. Structural parameters such as internal surface area and surface-to-volume ratio of pores, pore size distribution, fractal dimension, and mean particle size have been calculated over a wide range of densities. Simulation results are in accordance with structural measurements. Molecular-dynamics simulations were also performed to provide a microscopic understanding of recent pioneering high-pressure experiments on silica glasses at NSLS. The simulations reveal a structural transition to a new high-pressure amorphous phase with corner- and edge-sharing SiO6 octahedra. Parallel algorithms were designed for an initio quantum dynamics approach to materials simulations. With this approach, we have investigated the nature of electron transport in materials. We have also developed a tight-binding MD approach to investigate the influence of orientational disorder on structural correlations and phonon spectra of C60 solid. Results agree with neutron-scattering measurements. Currently, large-scale MD simulations (approximately 10(exp 6) atoms) are being performed to investigate the relation between structure, dynamics, and mechanical properties and the influence of environment, composition, and stress conditions on nanophase ceramics (Si3N4, SiC, TiO2, and Al2O3) and on silicates, aluminosilicates, and zeolites. This invention is a robotic joint which is operated by inflatable bladders and which can be used in applications where it is desired to move or hold an object. A support block supports an elongated plate to which is pivotally attached a finger. A tension strip passes over a lever attached to the finger and is attached at its ends to the support block on opposite sides of the plate. Bladders positioned between the plate and the tension strip

on opposite sides of the plate can be inflated by pumps to pivot the finger, with one of the bladders being inflated while the other is being deflated. Official Gazette of the U.S. Patent and Trademark Office

An assembly of an article and a polyimide is prepared. The assembly resists dimensional change, delamination, or debonding when exposed to changes in temperature. An article is provided. A soluble polyimide resin solution having a low coefficient of thermal expansion (CTE) was prepared by dissolving the polyimide in solvent and adding a metal ion-containing additive to the solution. Examples of the additive are: Ho(OOCCH3), Er(NPPA)3, TmCl3, and Er(C5H7O2)3. The soluble polyimide resin is combined with the article to form the assembly.

New, thermooxidatively stable polyimides were prepared from the reaction of aromatic dianhydrides containing isopropylidene bridging groups with aromatic diamines containing amide connecting groups between the rings. Several of these polyimides were shown to be semi-crystalline as evidenced by wide angle x ray scattering and differential scanning calorimetry. Most of the polyimides form tough, flexible films with high tensile properties. These polyimide films exhibit enhanced solubility in organic solvents.

A primary concern in modern fluid dynamics research is the experimental verification of computational aerothermodynamic codes. This research requires high precision and detail in the test model employed. Ceramic materials are used for these models because of their low heat conductivity and their survivability at high temperatures. To fabricate such models, slip casting techniques were developed to provide net-form, precision casting capability for high-purity ceramic materials in aqueous solutions. In previous slip casting techniques, block, or flask molds made of plaster-of-paris were used to draw liquid from the slip material. Upon setting, parts were removed from the flask mold and cured in a kiln at high temperatures. Casting detail was usually limited with this technique -- detailed parts were frequently damaged upon separation from the flask mold, as the molded parts are extremely delicate in the uncured state, and the flask mold is inflexible. Ceramic surfaces were also marred by 'parting lines' caused by mold separation. This adversely affected the aerodynamic surface quality of the model as well. (Parting lines are invariably necessary on or near the leading edges of wings, nosetips, and fins for mold separation. These areas are also critical for flow boundary layer control.) Parting agents used in the casting process also affected surface quality. These agents eventually soaked into the mold, the model, or flaked off when releasing the case model. Different materials were tried, such as oils, paraffin, and even an algae. The algae released best, but some of it remained on the model and imparted an uneven texture and discoloration on the model surface when cured. According to the present invention, a wax pattern for a shell mold is provided, and an aqueous mixture of a calcium sulfate-bonded investment material is applied as a coating to the wax pattern. The coated wax pattern is then dried, followed by curing to vaporize the wax pattern and leave a shell mold of the calcium sulfate-bonded investment material. The shell mold is cooled to room temperature, and a ceramic slip is poured therein. After a ceramic shell of desired thickness has set up in the shell mold, excess ceramic slip is poured out. While still wet, the shell mold is peeled from the ceramic shell to expose any delicate or detailed parts, after which the ceramic shell is cured to provide a complete, detailed, precision ceramic article without parting lines.

The program goals were to develop and demonstrate significant improvements in processing methods, process controls and non-destructive evaluation (NDE) which can be commercially implemented to produce high reliability silicon nitride components for advanced heat engine applications at temperatures to 1,370 C. The program focused on a Si3N4-4% Y2O3 high temperature ceramic composition and hot-isostatic-pressing as the method of densification. Stage 1 had as major objectives: (1) comparing injection molding and colloidal consolidation process routes, and selecting one route for subsequent optimization, (2) comparing the performance of water milled and alcohol milled powder and selecting one on the basis of performance data, and (3) adapting several NDE methods to the needs of ceramic processing. The NDE methods considered were microfocus X-ray radiography, computed tomography, ultrasonics, NMR imaging, NMR spectroscopy, fluorescent liquid dye penetrant and X-ray diffraction residual stress analysis. The colloidal consolidation process route was selected and approved as the forming technique for the remainder of the program. The material produced by the final Stage 2 optimized process has been given the designation NCX 5102 silicon nitride. According to plan, a large

number of specimens were produced and tested during Stage 3 to establish a statistically robust room temperature tensile strength database for this material. Highlights of the Stage 3 process demonstration and resultant database are included in the main text of the report, along with a synopsis of the NCX-5102 aqueous based colloidal process. The R and D accomplishments for Stage 1 are discussed in Appendices 1-4, while the tensile strength-fractography database for the Stage 3 NCX-5102 process demonstration is provided in Appendix 5. (AD-A271858) Avail: CASI HC A02

A process for producing patterned metal deposits on fluoropolymeric substrates is described. A metal ion-chelating organosilane is chemisorbed by self-assembly onto a fluoropolymer surface after radio-frequency glow discharge plasma surface hydroxylation. Positional modulation of the surface hydrophobicity is illustrated by wetting. The silane covalently binds an aqueous palladium catalyst, and subsequent electroless deposition yields homogeneous or patterned metal deposits that exhibit excellent adhesion to the fluoropolymer. DEVELOPMENT OF FUNDAMENTAL UNDERSTANDING OF FRICTION AND WEAR MECHANISMS BY ATOMIC-SCALE TRIBOLOGICAL STUDIES OF CERAMIC MATERIALS AND MULTILAYERED THIN FILMS Report, 1 Oct. 1992 - 30 Sep. 1993
Bharat Bhusham Oct. 1993 7 p
(Contract N00014-93-1-0067)
(AD-A271485) Avail: CASI HC A02/MF A01

The objective of the ongoing research program is to develop fundamental understanding of the friction and wear mechanisms through atomic-scale and micro-scale tribological studies of bulk ceramic materials and multilayered thin films in dry and boundary-lubricated conditions. We are studying the friction, scratching/wear and indentation behavior of engineering surfaces on atomic and microscales using on atomic force microscope (AFM)/ friction force microscope (FFM) and a nanoindenter. For comparisons, we are also conducting macro friction and wear tests on selected test specimens using a conventional pin-on-disk tribotester. Ceramics with various crystalline structures and multilayered thin films with a range of thicknesses and mechanical properties are planned for studies. Effect of thin layers of bonded and unbonded lubricant films on selected samples will be studied. A multiasperity contact model is being developed to predict the friction and wear for a multilayered solid in contact with another solid surface. The input to the model will be the measured micromechanical properties and 3-D surface topography statistics. DTIC

THEORETICAL AND EXPERIMENTAL STUDY OF THE WINDING OF A THIN PLASTIC FILM: THE ROLE OF AERODYNAMIC EFFECTS Ph.D. Thesis [ETUDE THEORIQUE ET EXPERIMENTALE DE L'ENROULEMENT D'UN FILM PLASTIQUE MINCE: ROLE DES EFFETS AERODYNAMIQUES]
Franck Bouquerel 1993 175 p In FRENCH Sponsored by Rhone-Poulenc Films, France
(ECL-93-04; ETN-93-94602) Avail: CASI HC A08/MF A02

A theoretical model to specify the critical conditions which induce instability phenomena, such as wrinkles, in thin plastic films as they are wound around a core when used as a substrate or as magnetic recording tape, is proposed. The model is based on a physical approach of winding: critical conditions are supposed to be strongly connected with the internal stresses. These stresses depend on winding conditions and foil properties. A general and realistic model based on a global approach of phenomena involved is proposed. The effect of the surface topography on air exhaust and radial properties of the wound foil are taken into account. Under these assumptions, prediction of new parameters such as thicknesses of the entrapped, exhaust or residual air layer become possible. For a large set of winding conditions and foil properties, good agreement is obtained between the theoretical and experimental results. Typical variation of the air interlayer thickness and stress fields are presented. It was observed that effects of winding velocity, nip force, foil tension, and foil roughness are all of the same order of magnitude, which is consistent with industrial knowhow. These results justify the global approach of the model. The model allows the final stress state and the air interlayers thickness to be computed as functions of the winding conditions (velocity, foil tension, and nip force) and the foil properties (bulk mechanical and superficial). A COMPARISON OF SULFURIC ACID/BORIC ACID ANODIZE AND CHROMIC ACID ANODIZE PROCESSES Final Report, Mar. 1992 - Jun. 1993
Stephen J. Spadafora and Frank R. Pepe 22 Jun. 1993 22 p
(AD-A271933; NAWCADWAR-93042-60) Avail: CASI HC A03/MF A01

Chromic acid anodizing (CAA) is an aluminum surface pretreatment currently used on Navy aircraft and weapon systems. This anodize process forms a thick oxide film which provides protection against environmental degradation. This is particularly important due to the severely corrosive naval aviation operational environment. Chromium VI, however, is a carcinogen and its wide-spread use as a corrosion inhibitor in this process is being restricted. The Navy has targeted chromated maintenance operations for reduction of hazardous waste generation. Several alternative candidates have been identified: phosphoric acid anodizing, Boeing Aerospace Corp.'s boric-sulfuric acid anodize (SBAA), and thin film sulfuric acid anodizing.

The Boeing SBAA process was selected for optimization and service demonstration. The Naval Air Warfare Center Aircraft Division Warminster analyzed the performance properties of SBAA and CAA both sealed and unsealed on various substrates with and without standard Navy coatings. DTIC

MECHANICAL PROPERTIES AND RELIABILITY OF SEMI-CRYSTALLINE POLYMERS Final Report
Leo Mandelkern 1993 4 p
(Contract N00014-87-J-1185)
(AD-A271591) Avail: CASI HC A01/MF A01

The major effort of this project has been the study of the physical and mechanical properties of crystalline polymers and the changes that take place over long-time periods. The study of the long-time crystallization, at ambient temperature, of a series of linear and branched polyethylenes showed a slow but steady density increase with time that could be demonstrated to be due to a decrease in the content of the liquid-like region and an increase in the partially ordered interfacial region. Significantly, the core-crystallinity level remains unaffected by the long time density increase. A detailed study of the overall crystallization kinetics of a set of model random copolymers, the hydrogenated polybutadienes, that covered a wide range in molecular weight and count content was completed. A basic understanding of the crystallization process in random copolymers, and of the structural factors which control long-time crystallization from the melt was developed. For the first time it was possible to separate the influence of molecular weight and co-unit content as independent variables that govern crystallization. DTIC

An oxidation resistant coating system is provided for the protection of superalloy gas turbine components. The chemistry of the coating is modified from that of prior coatings to increase the adherence of the protective oxide scale and to increase the strength and diffusional stability of the coating, while maintaining adequate resistance to corrosion by ingested salts. The coating and substrate material may be optimized to provide increased performance and operating life of the gas turbine. The coating of the invention consists essentially of ingredients in substantially the following ranges, expressed in weight percent: Cr, 15-35; Al, 8-20; Ta, 0-10; Ta + Nb, 0-10; Si, 0.1-1.5; Hf, 0.1-1.5; Y, 0-1; Co, 0-10; and sufficient Ni to bring the total to 100 percent. Most preferably, a coating designed to protect superalloy turbine blades and vanes such as single crystal components consists essentially of ingredients in about the following amounts, in weight percent: Cr, 20; Al, 11; Ta, 7; Hf, 1; Si, 1; Nb, Si, and Y, zero to trace amounts; and the balance being Ni. The coatings can be applied to the substrates by any convenient means which minimizes oxidation or other degradation of the coating during application. Preferably the coating is applied as an overlay, for example by plasma spraying, electron beam deposition, or sputtering. Author (CISTI)

(AD-A272805) Avail: CASI HC A03/MF A01

Amorphous (Al2O3)x(SiO2)y thin films have been grown by atmospheric pressure metal-organic chemical vapor deposition using the single source precursor Al(OSiEt3)32. Characterization by x-ray photoelectron spectroscopy indicated that the films consisted of a mixture of Al2O3, SiO2, and an aluminosilicate. The relative amount of each species was dependent on the deposition temperature and the carrier gas composition. Use of NH3 as the carrier gas resulted in the increased volatility of the precursor by the in situ formation of the low melting Lewis acid-base adduct Al(OSiEt3)3(NH3), however, no nitrogen incorporation was observed in these deposited films. ROTATIONAL ISOMERS OF Mo(VI) ALKYLIDENE COMPLEXES AND Cis/TRANS POLYMER STRUCTURE: INVESTIGATIONS IN RING-OPENING METATHESIS POLYMERIZATION Technical Report
John H. Oskam and Richard R. Schrock 20 Oct. 1993 49 p
(Contract N00014-92-J-1433)
(AD-A272647) Avail: CASI HC A03/MF A01

In the last few years well-defined metathesis catalysts of the general type M(NR)(CHR)(OR')2 (M=Mo or W) have proven useful in a variety of olefin metathesis studies, in part because the activity of catalysts can be varied systematically by altering the electron-withdrawing ability of the alkoxides. Complexes containing t-butoxides (OCMe3 and OCMe(Cf3)2 in particular), an arylimido ligand (often NAr, where Ar= 2,6-i-Pr2C6H3), and molybdenum have been the most versatile. In the area of ring-opening metathesis polymerization (ROMP) molybdenum complexes have been employed most often to prepare polymers from a variety of norbornenes and norbornadienes. Molybdenum complexes appear to tolerate a wide range of functionalities, are stable and active in a variety of solvents,and have been shown to produce polymers that are virtually all trans and highly tactic or all cis with a tactic bias of approx. 75%. Alkylidene rotational isomers or rotamers (eq 1) are found for many high-oxidation state alkylidene complexes. DTIC

POLYMERIZATION OF ENANTIOMERICALLY PURE 2,3-DICARBOALKOXY NORBORNADIENES AND 5,6-DISUBSTITUTED NORBORNENES BY WELL-CHARACTERIZED MOLYBDENUM ROMP CATALYSTS
Richard ODell, David H. McConville, Gretchen E. Hofmeister, and Richard R. Schrock 29 Oct. 1993 38 p
(Contract N00014-92-J-1433)
(AD-A272649; TR-22) Avail: CASI HC A03/MF A01

Preparing polymers with a regular primary structure is a prerequisite to ultimately controlling the properties of the bulk polymer in a systematic manner. Polymers prepared by ring-opening metathesis polymerization (ROMP) of norbornenes and norbornadienes employing classical metathesis catalysts are rarely regular. In contrast, it has been shown that 2,3-bis(trifluoromethyl) norbornadiene (NBDF6) and 2,3-dicarbomethoxy norbornadiene (DCMNBD) can be ring-opened with 'well-characterized' catalysts of the type Mo(CHCMe2R')(NAr)(OR)2 (R'= Me, Ph; Ar = 2,6-i-Pr2-C6H3) to give highly tactic (greater than 90%) high trans poly (NBDF6) and poly(DCMNBD) when OR = O-t-BU, and high cis poly (NBDF6) and poly (DCMNBD) with a tactic bias of approximately 75% (sigma m)c=0.75 when OR = OCMe(CF3)2. (The four possible regular structures of polymers of this type are shown in Scheme I.) It has been suggested that high trans poly (NBDF6) and high cis poly (NBDF6) prepared using the initiators mentioned above both have a syndiotactic bias (B and C, respectively) on the basis of the measurement of the value of the relaxed dielectric constant. MICROSTRUCTURAL MODELING AND TOUGHENING OF Si3N4 CERAMICS FOR HIGH TEMPERATURE ENGINE APPLICATIONS Final Report, 30 Aug. 1991 - 15 Oct. 1993
R. L. Yeckley Aug. 1993 30 p
(Contract DAAL04-91-C-0039)
(AD-A272897; ARL-CR-62) Avail: CASI HC A03/MF A01

R-curve behavior was achieved in hot isostatically pressed (HIP) silicon nitride with low additive levels. Two HIP densification processes which produced R-curve in HIP silicon nitride were demonstrated. The first densification process was extended soaks at 1840 deg C; the second included a pre-HIP sinter step. The strongest R-curve behavior was observed with the rare earth mixture of erbia-samaria, HIPed at 1840 deg C for 240 minutes. The fracture toughness approached 11 MPa-m(exp 1/2) at crack lengths of only 600 to 800 microns. Other rare earth combinations were

also evaluated. The final microstructure was influenced by the type of rare earths and silica content. The mixed rare earths resulted in a finer and higher aspect ratio microstructure than materials densified with yttria. The development work strongly suggests that HIP silicon nitride which combines the creep resistance of NT154 type materials with R-curve behavior is possible. DTIC

EFFICIENCY OF REVERSIBLE OPTICAL STORAGE IN AZO POLYMERS Technical Report
P. Rochon, J. Mao, A. Natansohn, and S. Xie 15 Nov. 1993 9 p
(Contract N00014-93-1-0615)
(AD-A272923; TR-4) Avail: CASI HC A02/MF A01

Optical information can be stored, erased or overwritten on polymer thin films using polarized light. The information is in the power probe beam. We have measured the efficiency of the writing beam in a number of polymer and copolymer films containing azobenzene dyes as side groups. In this paper we compare the results amongst the polymers we have synthesized. Preliminary results indicate that copolymers may be optimized to allow for the preparation of efficient thick films for erasable optical recording. DTIC

THE USE OF SCREENING TESTS IN SPACECRAFT LUBRICANT EVALUATION
Chris Kalogeras, M. Hilton, D. Carre, S. Didziulis, and P. Fleischauer 15 Oct. 1993 38 p
(Contract F04701-88-C-0089)
(AD-A272943; TR-93(3935)-6; SMC-TR-93-50) Avail: CASI HC A03/MF A01

A lubricant screening test fixture has been devised to obtain lubricant performance data in a timely manner. This fixture has been used to perform short-term tests on potential lubricants for several spacecraft applications. The results of these tests have saved time by producing qualitative performance rankings of lubricant selections prior to life testing. To date, this test fixture has been used to test lubricants for three particular applications: an oscillating scanner bearing, a harmonic drive actuator mechanism, and a reaction wheel support bearing. The qualitative results from these tests have been verified by life test results and have provided insight into the function of various antiwear additives. DTIC

RECENT DEVELOPMENTS IN AROMATIC AZO POLYMERS RESEARCH Technical Report
S. Xie, A. Natansohn, and P. Rochon 15 Nov. 1993 28 p
(Contract N00014-93-1-0615)
(AD-A272966; TR-1) Avail: CASI HC A03/MF A01

The photochemical and thermal cis to trans isomerization of aromatic azo groups covalently bonded within polymers and its practical consequences as well as some other recent applications are reviewed. The kinetics and mechanism of the isomerization of azo polymers are briefly presented and then several recent developments in azo polymers research are discussed. They include liquid crystallinity, nonlinear optical properties, monolayer assemblies and the light induced birefringence and dichroism. Some of the phase transitions of liquid crystalline azo polymers can be induced photochemically by the azo groups isomerization. Second order optical nonlinearity can be obtained in polymers with donor and acceptor substituted azo groups. Using the Langmuir-Blodgett technique, azo polymer monolayers can be built and used as 'command surfaces' of liquid crystal films. The light induced birefringence is a reorientation phenomenon which is a consequence of the trans-cis-trans isomerization. Future possible applications for a variety of practical devices, such as display devices, optical modulators, optical waveguides, holography, and reversible optical storage are mentioned. DTIC

AZO POLYMERS FOR OPTICAL STORAGE 3: EFFECT OF FILM THICKNESS ON NET PHASE RETARDATION AND WRITING SPEED Technical Report
P. Rochon, D. Bissonnette, A. Natansohn, and S. Xie 15 Nov. 1993 17 p
(Contract N00014-93-1-0615)
(AD-A272994; TR-5-ONR) Avail: CASI HC A03/MF A01

The optical writing phenomenon observed on azoaromatic containing polymer thin films exhibited a writing rate which was proportional to the intensity of the writing beam. This property of the mechanism for optically inducing dichroism and birefringence directly results in nonlinear optical behavior in the thin film. The net phase retardation obtainable and writing rates are functions of the thin film thickness which reflect this nonlinear behavior. DTIC

STRESS-INDUCED CRACKING OF FLUOROCARBON RUBBER MTL-0002 AFTER EXPOSURE TO DS-2 Final Report
Karen M. Kinsley Sep. 1993 23 p
(AD-A271753; ARL-TR-219) Avail: CASI HC A03/MF A01

Fluorocarbon rubber 0002 (MTL-0002) was found to be susceptible to stress-induced cracking (SIC) when exposed to the standard decontaminant DS-2. In this report, several tensile tests were conducted upon this rubber and related fluorocarbon elastomers after exposure to DS-2 and its components. It was found that diethyl enetriamine, a DS-2 component, was responsible for the formation of cracks under tension. Of the vulcanizates tested, MTL-0002 was the most susceptible to SIC after a one-half hour immersion in DS-2, but I. B. Moore V7D failed at lower stress levels after 24 hours of immersion in DS-2. It is suggested that changing the proportion of magnesium oxide and calcium hydroxide in the recipe and altering the press curing temperature time may enhance the resistance to SIC of MTL-0002. DTIC

INTELLIGENT PROCESSING OF FERROELECTRIC THIN FILMS Annual Report, 2 May 1992 - 31 Jul. 1993
Gene Haertling, Eric Skaar, Fei-Ling Wang, Joyti Guha, and David Dausch 3 Sep. 1993 242 p
(Contract N00014-91-J-1508)
(AD-A272518) Avail: CASI HC A11/MF A03

The work described in this report covers the second year of a three-year program involving intelligent processing of ferroelectric thin films and bulk materials. It is presented in seven parts dealing with automation, powder processing, bulk materials characterization, thin film fabrication and evaluation, electrooptic behavior of thin films, and published work. In regard to process automation and intelligence, the two-conductor ac resistance probe was tested for reading stability and response time. Both requirements were easily met, and simulated batching experiments were carried out. The fluid flow pattern for the batching system has required special attention and optimization. Programming of the device drivers which are needed to link the computer and its neural network has now been completed, thus paving the way for making the system totally operational. DTIC

EVALUATION OF ELECTROCONDUCTIVITY OF TWO SURFACE PAINTS FOR SPACECRAFT
Lu Yusun, Li Hua, Han Xiao-Wen, and Chen Wen-Ying 5 Nov. 1993 15 p Transl. into ENGLISH from Zhongguo Kongjian Kexue Jishu (China), v. 3, 1989 p 41-46
(AD-A273063; FASTC-ID(RS)T-0560-93) Avail: CASI HC A03/MF A01

This article briefly discusses the manufacturing process for two surface paints (used on spacecraft): No. 956 gray paint, and No. 956 green paint. Experimental studies were conducted on both paints at room temperatures in variations of electroconductivity in space environments: in a simulated space vacuum, under electron radiation and under solar radiation. From the experimental results, the states of both surface paints used in orbit can be predicted. In addition, the possibility of using such paints in high orbit is accepted. DTIC

DYNAMICS OF ADSORBED, SWOLLEN BLOCK COPOLYMERS Interim Report, 1 Jan. 1991 - 31 Oct. 1993
Brijnaresh Sinha, Frank D. Blum, and Fredrick C. Schwab 20 Oct. 1993 25 p
(Contract N00014-91-J-1274)
(AD-A272013; UMR-FDB-32) Avail: CASI HC A03/MF A01

Deuterium NMR relaxation times of specifically deuterated block terpolymers of 2-vinyl pyridine (VP), styrene (S), and deuterostyrene (DS) were measured for the polymers in solution and on silica as a function of temperature and solvent. The block polymers were attached to the silica through the VP segments; the S and DS segments were extended into the solution. In a thermodynamically poor solvent, such as carbon tetrachloride, the relaxation times were consistent with the S segments on the surface-bound polymer being less mobile than their counterparts in solution. This is in contrast with their behavior in toluene (previously reported), where the styrene segments of the surface-bound polymer appeared to be more mobile than in solution. The results demonstrate that the solvent quality may have a dramatic effect on the dynamics of the chain segments of the surface-bound polymer. In a mixture of solvents, namely carbon tetrachloride and methanol, there was evidence for more mobile S segments in the surface-bound polymer, however, the VP units also had additional mobility due to the presence of the methanol. The relaxation times were also used, along with the model of Hall and Helfand, to determine the motional parameters and spectral densities for the polymers in the different s stems. DTIC

POLYMERIC NITROGEN
C. Mailhiot, L. H. Yang, A. K. McMahan, and T. W. Barbee, III Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE93-040544; UCRL-JC-110049-Rev-2; CONF-930676-50-Rev-2) Avail: CASI HC A02/MF A01

The equilibrium phase boundary between single-bonded, threefold-coordinated polymeric forms of nitrogen, and the observed, triple-bonded diatomic phases, is predicted to occur at relatively low (50 +/- minus) 15 GPa) pressure. This conclusion is based on extensive local-density functional total-energy calculations for polymeric structures (including that of black phosphorus, and another with all gauche dihedral angles) and diatomic structures (including that of the observed high-pressure epsilon-N2 phase). Our results suggest that the diatomic phase of nitrogen, observed up to 180 GPa and room temperature, is metastable at these conditions, and that such hysteresis enhances the prospects for the existence of a metastable polymeric form of nitrogen at ambient conditions. OPTICALLY INDUCED BIREFRINGENCE IN COPOLYMERS AND BLENDS CONTAINING AZOBENZENE GROUPS Technical Report
D. Brown, A. Natansohn, P. Rochon, and S. Xie 15 Nov. 1993 7 p
(Contract N00014-93-1-0615)
(AD-A273085; TR-6) Avail: CASI HC A02/MF A01

The birefringence level in a copolymer or a blend containing disperse red 1 acrylate or methacrylate structural units depends not only on the molar fraction of the azo component, but also on the type of the next-neighbor on the chain. Copolymers behave quite differently from blends. Also, if a few azo groups are neighboring each other, the induced birefringence is more stable. DTIC

The properties of new, high temperature optical materials based on dye-doped Ultradel 9000D polyimides are presented. Ultradel 9000D is a soluble, pre-imidized, fluorinated polymer with properties optimized for integrated optical applications. When thermally or photochemically cross-linked, it has a Tg approaching 400 C and retains excellent optical transparency as measured by both waveguide loss spectroscopy (WLS) and photothermal deflection spectroscopy (PDS). The agreement between WLS and PDS data indicates that losses in polyimides are due to absorption, not scattering. Two thermally stable, donor-acceptor oxazole-based dyes were designed, synthesized, and doped into the polyimide at concentrations up to 25 percent by weight. The Tg of the doped polymers decreased from the neat polymer, but remained above 300 C. The effects of doping on the dielectric constant, refractive index, and coefficient of thermal expansion of the polyamide are presented. The oxazoles also photobleach and thereby, providean additional means of photodefining waveguides in these materials. DOE

(DE93-040280; ANL/MSD/CP-80610; CONF-930703-32) Avail: CASI HC A02/MF A01

Influence of radiation damage (gamma, electron, neutron) on mechanical properties of fiber reinforced plastics (FRP's) has been investigated. Different types of FRP's (two or three dimensional E-, S- or T-glass fiber reinforcement, epoxy or bismaleimide resin) have been irradiated at room temperature with 2 MeV electrons and Co-60 gamma-rays up to 1.8 x 10 exp 8 Gy as well as with different reactor spectra up to a fast neutron fluence of 5 x 10(exp 22) m(exp -2) (E greater than 0.1 MeV). Tensile and intralaminar shear tests were carried out on the irradiated samples at 77 K. Some samples were irradiated at 5 K and tested at 77 K with and without an annealing cycle to room temperature. Results on the influence of these radiation conditions and of warm-up cycles on the mechanical properties of FRP's are compared and discussed. DOE

SHOCK COMPRESSION OF LOW-DENSITY FOAMS
N. C. Holmes Jul. 1993 6 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-48)
(DE93-040545; UCRL-JC-113766; CONF-930676-49) Avail: CASI HC A02/MF A01

Shock compression of very low density micro-cellular materials allows entirely new regimes of hot fluid states to be investigated experimentally. Using a two-stage light-gas gun to generate strong shocks, temperatures of several eV are readily achieved at densities of roughly 0.5-1 g/cm(exp 3) in large, uniform volumes. The conditions in these hot, expanded fluids are readily found using the Hugoniot jump conditions. We will briefly describe the basic methodology for sample preparation and experimental measurement of shock velocities. We present data for several materials over a range of initial densities. This paper explores the applications of these methods for investigations of equations of state and phase diagrams, spectroscopy, and plasma physics. Finally, we discuss the need for future work on these and related low-density materials. DOE

PREPARATION OF CONCRETE SPECIMENS FOR MICROSTRUCTURAL IMAGE ANALYSIS STUDIES
Paula Raivio *In its* Symposium on Microscopy and Image Analysis of Building Materials 1993 p 5-11 (For primary document see N94-21890 05-27)
Copyright Avail: CASI HC A02/MF A01

The preparation of concrete specimens for microstructural image analysis studies in incident light, transmission fluorescent light and backscattered electron imaging, is reported. The preparation of thick concrete sections for automatic air pore analysis in incident light is considered. For this the concrete should be solid with minor cracks and weak areas. The specimens are roughly 80 by 80 by 10 cu mm in size. The use of transmitted fluorescent light to study impregnated concrete sections requires thin samples. These are cut to roughly 30 by 50 by 10 cu mm. One side is treated with ethanol, after which it is glued onto a glass slide and impregnated with epoxy mixed with fluorescent dye. Polished section preparation, which

is similar to thin section preparation, is necessary to produce scanning electron microscope images. ESA

OPTICAL AIR PORE ANALYSIS

Erkki Vesikari *In its* Symposium on Microscopy and Image Analysis of Building Materials 1993 p 12-21 (For primary document see N94-21890 05-27)

Copyright Avail: CASI HC A02/MF A01

Methods for transforming direct measurement data into more refined data of the pore structure of concretes are discussed. The optical air pore analysis system considered consists of an optical microscope, an automatic microscope stage with control unit, a television (TV) camera, an image processing unit and TV monitor, a desk top computer with printer and a graphic plotter. A method for calculating real three dimensional pore size distribution and estimates for the total number of pores and average distance between pores is presented. A two dimensional distribution obtained by an optical air pore analysis can be made three dimensional by an automatic transformation process. A better estimate for the total number of pores can also be obtained. A measure for the average distance between pores based on improved estimation of the number of pores was developed. The average distance between pores showed a better coherence with freeze thaw resistance test results than did Power's spacing factor. ESA

Image analysis was applied for quantification and verification of microstructural features of mature cement paste hydrated isothermally in the range 5 to 50 C. The image analysis provided quantitative information on the amount of unreacted cement, calcium hydroxide, other hydration products and pores above approximately 3500 A. It is shown from backscattered electron images that the hydration temperature influences the distribution of hydration products in the paste matrix. At the higher temperatures, dense hydration shells were formed around the hydrating grains, leaving an outer product phase of high capillary porosity. The image analysis showed that the temperature had a significant effect on the porosity. This can be attributed to the higher porosity of the outer product phase. In contrast to other reports, it could not be demonstrated that the hydration product formed at elevated temperatures contained less chemically bound water. ESA

DETERMINATION OF PORE STRUCTURE OF CONCRETE FROM THIN SECTIONS BY IMAGE ANALYSIS

Kai Tattari *In its* Symposium on Microscopy and Image Analysis of Building Materials 1993 p 41-46 (For primary document see N94-21890 05-27)

Copyright Avail: CASI HC A02/MF A01

A method was developed for analysis with an IMIX image analyzer of thin section images detected by a video camera and microscope. Image analysis was used for the determination of quantitative parameters characterizing microcracks and the air-void system of concrete. The analysis results were compared with those results from the reference images. Relative deviations were calculated for each pair of images. The parameters were the sum total of pores and cracks and the area fraction. The mean values and variances of the relative deviations were calculated so as to include each pair of images. In this way it was possible to find the best combination for the erosion and dilation. ESA

MICROSTRUCTURE IN MORTAR: A SUMMARY OF A NEW PROJECT OF RESEARCH

Thomas Carlsson *In* Technical Research Centre of Finland, Symposium on Microscopy and Image Analysis of Building Materials 1993 p 47-50 (For primary document see N94-21890 05-27)

Copyright Avail: CASI HC A01/MF A01

A project aimed at the study of how different 'factors' influence the 'structure' and how the structure influences the 'qualities' of material and combinations of material within the field of render and masonary is summarized. The basic thought is that structural analysis will be able to forsee different qualities and consequences, especially long term. The project bases itself solely on microscope studies. Structure influencing factors that will be studied include air entraining agents in mortar, suction in the background at the moment of rendering/brick laying, frost load in mortar and brick. The structure dependent qualities which will be determined are frost resistance, strength and adhesion. ESA

TECHNIQUES FOR PRODUCING FREE-STANDING THIN FILMS ON FRAMES

J. H. Aubert and W. F. McNamara 1993 5 p Presented at the 9th Target Fabrication Specialists Meeting, Monterey, CA, 9 May 1993 (Contract DE-AC04-76DP-00789)

(DE93-041144; SAND-93-0998C; CONF-9305283-1) Avail: CASI HC A01/MF A01

The procedures of vapor-deposition polymerization, spin coating and orientation-dependent etching have been employed to make free-standing thin films of Parylene-N, Parylene-D, polystyrene, polycarbonate and perfluoro-dimethyl-dioxole / tetrafluoroethylene copolymer (Teflon(reg sign) AF-1600). The polymeric materials were vapor-deposited or spin-coated onto substrates of polished single-crystal silicon (wafers) and removed on frames of various shapes and sizes after application of adhesive and an etching process using potassium hydroxide. Thicknesses range from 2000 A to 12000 A. DOE

DYNAMIC PROPERTIES OF CERAMIC MATERIALS

D. E. Grady and J. L. Wise Sep. 1993 54 p

(Contract DE-AC04-76DP-00789)

(DE94-000654; SAND-93-0610) Avail: CASI HC A04/MF A01

Controlled impact methods have been employed to obtain dynamic response properties of armor materials. Experimental data have been obtained for high-strength ceramics. Continued analysis of time-resolved velocity interferometer measurements has produced systematic material-property data for Hugoniot and release response, initial and post-yield strength, pressure-induced phase transformation, and dynamic fracture strength. A new technique has been developed to measure hydrodynamic properties of ceramic through shock-wave experiments on metal-ceramic composites and data obtained for silicon carbide. Additional data on several titanium diboride ceramics and high-quality aluminum oxide ceramic have been acquired, and issues regarding the influence of microstructure on dynamic properties have emerged. Comparison of dynamic (Hugoniot elastic limit) strength and indentation hardness data has been performed and important correlations revealed. Innovative impact experiments on confined and unconfined alumina rods using axial and transverse VISAR diagnostics have been demonstrated which permit acquisition of multiaxial dynamic response data. Dynamic failure properties of a high-density aluminosilicate glass, similar in composition to the intergranular glassy phase of some aluminas, have been investigated with regard to yield, spall, and failure-wave propagation. DOE

THE OPTICAL CONSTANTS AND SPECTRAL SPECULAR REFLECTIVITY OF HIGHLY ORIENTED PYROLYTIC GRAPHITE (HOPG)
M. A. Havstad, M. A. Schildbach, and W. McLean, II Aug. 1993 26 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract W-7405-eng-48)
(DE93-040546; UCRL-JC-111969-Rev-1; CONF-930830-11-Rev-1) Avail: CASI HC A03/MF A01

Measurements of the specular reflectivity and the optical constants of highly ordered pyrolytic graphite (HOPG) have been made using two independent optical systems. The first measures reflectance (at 1.06 microns and 293 K) by comparing the intensity of a laser beam before and after reflecting off the sample. The second determines the complex index of raft-action (from 0.55 to 8.45 micron with sample temperatures of 293, 480, 900, and 1300 K) by ellipsometry. Agreement between the two methods is good. Moderate reflectivities are observed over the full spectral range of measurement: the spectral directional-hemispherical reflectivity at normal incidence varies from 0.41 at 0.55 micron to 0.74 at 8.45 microns. The components of the complex index of refraction increase smoothly with wavelength. The index of refraction increases from 3.10 at 0.55 micron to 7.84 at 8.45 microns. The extinction coefficient varies from 2.01 to 6.66 over the same range. DOE

HIGH TEMPERATURE SIZE SELECTIVE MEMBRANES
S. F. Yates and A. X. Swamikannu 1993 7 p Presented at the Coal-Fired Power Systems 1993 Advances in IGCC and PFBC Review Meeting, Morgantown, WV, 28-30 Jun. 1993
(Contract DE-AC21-92MC-29245)
(DE93-019865; DOE/MC-29245/93/C0205; CONF-9306148-19) Avail: CASI HC A02/MF A01

The high temperature membrane, capable of operation above 550 C, is designed to be a composite membrane composed of a thin layer of a size selective membrane supported by a microporous ceramic support. The kinetic diameters of H2 and CO2 are 2.96 A and 4.00 A. The thin layer will be made from carbon molecular sieve (CMS) whose pore size will be controlled to be less than 4 A. The membrane will be truly size selective and be impermeable to carbon dioxide. The membrane will have higher selectivity than membranes which operate on Knudsen diffusion mechanism. The ceramic support will be fabricated from Allied Signal's proprietary Blackglas (trademark) resin. The ceramic material, noted for its high thermal and oxidative resistance, has a coefficient of thermal expansion which matches closely that of CMS. The close match will insure mechanical integrity when the membrane is subjected to thermal cycles. The CMS layer will be produced by controlled pyrolysis of polymeric precursors. Pore size will be suitably modified by post-treatments to the carbon. The composite membrane will be tested for its permeation properties at 550 C or higher. Thermal, mechanical, and chemical stability of the membrane will be assessed. We have produced several samples of CMS from polymeric precursors. We have initiated work also on the preparation of microporous supports from Blackglas (trademark) resin. We have completed the design of the high temperature membrane pilot plant. The membrane cell was fabricated out of two kinds of stainless steel. The inner parts are made of SS 316 and the outer ring made of SS 420. The greater thermal expansion of the SS 316 will help obtain a leak free seal at the operating temperatures. DOE

TENSILE STRENGTH OF FIBER REINFORCED PLASTICS AT 77K IRRADIATED BY VARIOUS RADIATION SOURCES
K. Humer, H. W. Weber (Atominstitut der Oesterreichischen Hochschulen, Vienna.), E. K. Tschegg (Technische Univ., Vienna, Austria.), and S. Egusa (Japan Atomic Energy Research Inst., Takasaki.) Aug. 1993 13 p Presented at the 6th International Conference on Fusion Reactor Materials, Stresa, Italy, 27 Sep. - 1 Oct. 1993
(Contract W-31-109-eng-38)
(DE93-040826; ANL/MSD/CP-79440; CONF-930928-5) Avail: CASI HC A03/MF A01

The influence of radiation damage on the mechanical properties of fiber reinforced plastics (FRP's), which are considered as candidate materials for the insulation of superconducting magnets for nuclear fusion reactors, has been investigated. Different types of FRP's (epoxies, bismaleimides; two- and three-dimensional reinforcement structures with E-, S-, or T-glass fibers) has been included in the test program. Three aspects of our present results are discussed in detail. The first is related to an assessment of the tensile strength and its radiation dependence under the influence of strongly varying radiation conditions. The second aspect refers to low temperature (approximately 5 K) reactor irradiation of selected materials. In this case, identical sets of tensile test samples were transferred into the tensile testing machine, one without warming-up to room temperature and the other after an annealing cycle to room temperature. Finally, a comparison between the radiation response of different materials is made. It turns out that the three-dimensionally reinforced bismaleimide shows the smallest degradation of its tensile properties under all irradiation conditions. DOE

(AD-A271060; MRL-TN-627; DODA-AR-008-232) Avail: CASI HC A03/MF A01

The effect of a new organo-copper burn rate catalyst on the aging properties of an HTPB/AP based composite propellant has been studied and compared with a similar propellant containing copper chromite. The degradation of the propellant surface under conditions of thermo-oxidation was studied by monitoring oxygen uptake using a gravimetric technique. The oxidative induction times for the reaction were determined for a series of elevated temperatures and the data used to predict the storage life of the propellant at ambient temperatures using an Arrhenius plot. It was shown that the storage life of a copper chromite propellant was approximately 7.5 years at 20 C while the corresponding organo-copper propellant had a storage life of approximately 49 years. Domestic transportation fuels are almost exclusively derived from petroleum and account for about two-thirds of total U.S. petroleum consumption. In 1990, more than 40% of the petroleum used domestically was imported. Because the United States has only 5% of the world's petroleum reserves, and the countries of the Middle East have about 75%, U.S. imports are likely to continue to increase. With our heavy reliance on oil and without suitable substitutes for petroleum-based transportation fuels, the United States is extremely vulnerable, both strategically and economically, to fuel supply disruptions. In addition to strategic and economic affairs, the environmental impacts of our use of petroleum are becoming increasingly evident and must be addressed. The U.S. Department of Energy's (DOE's) Office of Energy Efficiency and Renewable Energy (EE), through its Biofuels Systems Division (BSD), is addressing these issues. The BSD is aggressively pursuing research on biofuels-liquid and gaseous fuels produced from renewable domestic feedstocks such as forage grasses, oil seeds, short-rotation tree crops, agricultural and forestry residues, algae, and certain industrial and municipal waste streams. COMPATIBILITY AND EFFICACY OF BIOCIDES QUALIFIED UNDER MILITARY SPECIFICATION MIL-S-53021 Interim Report, Oct. 1992 - Aug. 1993
S. R. Westbrook and M. L. Alexander Sep. 1993 24 p
(Contract DAAK70-92-C-0059; DA Proj. 1L2-63001-D-150)
(AD-A271496; BFLRF-282) Avail: CASI HC A03/MF A01

The Army has three fuel biocides qualified under specification MIL-S-53021. The military's aviation kerosene, JP-8, also contains an icing inhibitor additive that has some biocidal activity. The relative effectiveness and compatibility of these additives have never been investigated. This study was conducted to evaluate the efficacy of the individual biocides as well as the possible interactions (either synergistic or antagonistic) between these biocides and the icing inhibitor additive. Each of the qualified biocides was evaluated using standard microbiological techniques to determine additive efficacy and compatibility with other fuel additives. The relative effectiveness of the qualified additives was determined. The interactions of the biocides with the icing inhibitor additive in JP-8 were also investigated. DTIC

This research program produced detailed information concerning the reactions of atoms with azide radicals, amines, aminyl radicals, and isocyanates, These processes release substantial amounts of energy and are constrained (by angular momentum conservation) to substantial amounts of energy and are constrained (by angular momentum conservation) to transfer processes generate products in specific states. In addition, reactions and energy transfer processes involving excited nitrene radicals were studied and the rates and mechanisms of several such processes were determined. The information generated provides insight into the fundamental behavior of nitrogen-halogen systems, and is relevant to the development of new lasers. DTIC

EVALUATION OF PRE-EXTRACTION ANALYTICAL HOLDING TIMES FOR NITROAROMATIC AND NITRAMINE EXPLOSIVES IN WATER Special Report
Clarence L. Grant, Thomas F. Jenkins, and Susan M. Golden Aug. 1993 18 p
(AD-A271547; Rept-93-24; ENAEC-TS-CR-93096) Avail: CASI HC A03/MF A01

A study was conducted to experimentally evaluate the maximum acceptable pre-extraction analytical holding times (MHT's) for three nitroaromatic compounds and two nitramines in water. Three fortified waters (reagent-grade water, ground water, and surface water) were utilized in the study. Analytes investigated were HMX, RDX, TNB, TNT, and 2,4-DNT, all at the low micrograms/L level. Subsamples of each water sample were held for periods of 0, 3, 7, 14, 28, and 70 days at either room temperature (22 C) or under refrigeration (2 C). Samples were analyzed by RPHPLC without preconcentration. The two nitramines, HMX and RDX, were stable over the entire period for all waters under both storage temperatures. For the three nitroaromatics (TNB, TNT, and 2,4-DNT) the results were very different. For the surface water, significant losses of TNB and TNT occurred in only a day or two, even under refrigeration. Loss of these analytes was accompanied by an increase in the concentration of their microbiological degradation products 3,5-dinitro aniline and 4-amino-2,6-dinitro toluene, respectively. The rate of loss of 2,4-DNT was much slower in the surface water than for either TNB or TNT. The rates of loss of the three nitroaromatics were much slower in the reagent-grade water and ground water than in the surface water. The recommended MHT for nitroaromatics and nitramines in relatively sterile water samples is 50 days under refrigeration. Surface water sample, or samples likely to have significant microbial activity, should be preserved in the field prior to shipment or analyzed on-site, or the loss of TNB and TNT is likely to be significant. SURFACE SCIENCE AND MODELING STUDIES OF ENDOTHERMIC FUELS CATALYSIS Final Report, 1 Aug. 1990 - 31 Jul. 1993
Bruce E. Koel and Emily A. Carter 10 Oct. 1993 24 p
(Grant AF-AFOSR-0331-90)
(AD-A272850; AFOSR-93-0844TR) Avail: CASI HC A03/MF A01

A description is provided of experimental results from surface science studies and insight from theoretical and modeling studies for new catalysts for endothermic fuels. Our work has focused on providing fundamental information concerning the thermochemistry, kinetics, and mechanism of the dehydrogenation of methylcyclohexane (MCH) to toluene over Pt and Pt alloys or intermetallic compounds. Chemisorption and adsorption kinetics measurements reveal that alkali adatoms or alloys of Pt can promote selectivity in dehydrogenation reactions that yield benzene or toluene. In addition, a new apparatus with a reaction antechamber was constructed that allows catalytic reaction rates to be measured on surfaces that are thoroughly characterized by surface analytical methods. Ab-initio calculations were performed for simple models of alloy catalysts, e.g., Pt2, Pt3, PtZr, Pt3Zr, Zr-H, Pt-H, Zr-CH3, and Pt-CH3. Quasiempirical valence bond (QVB) calculations were done for the dehydrogenation of MCH on Pt. In addition, new tools were developed for treatments of electron correlation required for these bimetallic catalysts. Two computer programs were also developed

to predict accurately the barriers and calculate the pre-exponential factors that appear in the Arrhenius expression for the rate constant in order to predict kinetics from first principles. DTIC

POWDERED ALUMINUM AND OXYGEN ROCKET PROPELLANTS: SUBSCALE COMBUSTION EXPERIMENTS
Mike L. Meyer Dec. 1993 12 p Presented at the 30th JANNAF Combustion Subcommittee Meeting, Monterey, CA, 15-19 Nov. 1993; sponsored by the Joint Army-Navy-NASA-Air Force Combustion Subcommittee
(RTOP 232-01-OA)
(NASA-TM-106439; E-8281; NAS 1.15:106439) Avail: CASI HC A03/MF A01

Aluminum combined with oxygen has been proposed as a potential lunar in situ propellant for ascent/descent and return missions for future lunar exploration. Engine concepts proposed to use this propellant have not previously been demonstrated, and the impact on performance from combustion and two-phase flow losses could only be estimated. Therefore, combustion tests were performed for aluminum and aluminum/magnesium alloy powders with oxygen in subscale heat-sink rocket engine hardware. The metal powder was pneumatically injected, with a small amount of nitrogen, through the center orifice of a single element O-F-O triplet injector. Gaseous oxygen impinged on the fuel stream. Hot-fire tests of aluminum/oxygen were performed over a mixture ratio range of 0.5 to 3.0, and at a chamber pressure of approximately 480 kPa (70 psia). The theoretical performance of the propellants was analyzed over a mixture ratio range of 0.5 to 5.0. In the theoretical predictions the ideal one-dimensional equilibrium rocket performance was reduced by loss mechanisms including finite rate kinetics, two-dimensional divergence losses, and boundary layer losses. Lower than predicted characteristic velocity and specific impulse performance efficiencies were achieved in the hot-fire tests, and this was attributed to poor mixing of the propellants and two-phase flow effects. Several tests with aluminum/9.8 percent magnesium alloy powder did not indicate any advantage over the pure aluminum fuel. Author

CHARACTERISTICS OF SHOCK-COMPRESSED CONFIGURATION OF Ti AND Si POWDER MIXTURES
N. N. Thadhani (Georgia Inst. of Tech., Atlanta.), E. Dunbar (New Mexico Inst. of Mining and Technology, Socorro.), and R. A. Graham 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018857; SAND-93-0510C; CONF-930676-36) Avail: CASI HC A01/MF A01

Shock-compression recovery experiments were performed on mixtures of Ti and Si powders of fine, medium, and coarse morphology, and packed at different initial densities, using the Sandia Momma and Poppa Bear fixtures with Baratol explosive. The shock-compressed configuration revealed characteristics typical of either chemically reacted material with fine equiaxed grains, or unreacted material with densely packed Ti and Si particles. The unreacted configuration showed that Ti particles were extensively deformed, irrespective of powder morphology and shock conditions generated by either fixture. In contrast Si particles showed different characteristics depending on the powder morphology, packing density, and shock conditions. The microstructural characteristics of unreacted configuration of Ti and Si powder mixtures were investigated. Mechanistic processes occurring prior to the inception of shock-induced chemical reactions in this system are described. DOE

CURRENT SITUATION IN DEVELOPING PETROLEUM SUBSTITUTING ENERGY (THE UNITED KINGDOM)
Mar. 1993 72 p
(DE94-714897; NEDO-P-9203) Avail: CASI HC A04/MF A01

A survey was made to identify the trends in developing petroleum energy substitutes in the United Kingdom. The UK has abundant coal resources, produces petroleum and natural gas in addition, and is the only energy self-sustaining country in the EC. However, coal for power generation was replaced with coal imports and natural gas because of inferior price competitiveness. The coal mine close-down bill has turned to a social problem. Petroleum is also losing its price competitiveness as the oil reservoir beds go deeper and deeper. Demand for natural gas is increasing because of the new consolidation cycle type gas turbine power generation, but natural gas will be depleted in 30 years. Building new nuclear power plants has been discontinued. Government subsidies are sought for developing wave and wind power utilization to cope with the downward trend in energy self-sufficiency. With respect to harmony with environment, the government is attempting to solve the matter by applying the policies of energy conservation and renewable energy development. The energy saving policies are being promoted in power generation, power distribution, commerces and industries, buildings, and electric products. For renewable energies, the Non-Fossil Fuel Obligation taxation system has already been applied extensively. DOE

EVAPORATION OF A SODIUM TELLURITE MELT IN THE JAMIC LOW GRAVITY DROP SHAFT Final Report
Chandra S. Ray, Delbert E. Day, Masaki Makihara, and Junji Hayakawa 1 Oct. 1993 44 p
Avail: CASI HC A03/MF A01

A sodium-tellurite (Na2O.4TeO2) glass, fused to a platinum wire heating coil, was evaporated in low gravity in the JAMIC drop shaft. The primary objectives were to: gain a better understanding of the evaporation mechanism from a melt surface which could improve glass melting techniques presently used on earth, obtain information for the growth of solid particles from vapor, and study the feasibility of preparing chemically pure spherical particles (ranging from several nanometers to micrometers in size) which could have application in medicine (radiotherapy of malignant tumors), optical communications, and as advanced composite materials. A Na2O.4TeO2 glass was selected as a model glass for this investigation primarily for the reason that it melts at a relatively low temperature (less than 700 C) and, therefore, only a nominal amount of electrical power was needed to conduct these experiments. Also, the tellurite glasses possess unique optical and chemical properties which make them potential candidates for practical applications such as glass to metal seals, infrared optical fibers, laser hosts, paramagnetic generators, and optical shutters. The samples from each drop shaft experiment were returned to UMR for analysis. Interesting results on the growth of particles from the vapor phase and for the crystallization of a Na2O.4TeO2 melt in low gravity were obtained. Some of the results are surprising (unexpected) and additional experiments are recommended for verifying these preliminary results. Derived from text

The Digital Wireless Control System (DWCS) is designed to initiate high explosives safely while using a wireless remote control system. Numerous safety features have been designed into the fire control system to mitigate the hazards associated with remote initiation of high explosives. These safety features range from a telemetry (TM) fire control status system to mechanical timers and keyed power lockout switches. The environment, safety, and health (ES&H) Standard Operating Procedure (SOP) SP471970 is intended as a guide when working with the DWCS. This report describes the Digital Wireless Control System and outlines each component's theory of operation and its relationship to the system. DOE

ALTERNATIVE REFRIGERANTS AND REFRIGERATION CYCLES FOR DOMESTIC REFRIGERATORS
J. R. Sand, C. L. Rice, and E. A. Vineyard Dec. 1992 142 p
(Contract DE-AC05-84OR-21400)
(DE93-040481; ORNL/M-2270) Avail: CASI HC A07/MF A02

This project initially focused on using nonazeotropic refrigerant mixtures (NARM's) in a two-evaporator refrigerator-freezer design using two stages of liquid refrigerant subcooling. This concept was proposed and tested in 1975. The work suggested that the concept was 20% more efficient than the conventional one-evaporator refrigerator-freezer (RF) design. After considerable planning and system modeling based on using a NARM in a Lorenz-Meutzner (L-M) RF, the program scope was broadened to include investigation of a 'dual-loop' concept where energy savings result from exploiting the less stringent operating conditions needed to satisfy cooling of the fresh food section. A steady-state computer model (CYCLE-Z) capable of simulating conventional, dual loop, and L-M refrigeration cycles was developed. This model was used to rank the performance of 20 ozone-safe NARM's in the L-M refrigeration cycle while key system parameters were systematically varied. The results indicated that the steady-state efficiency of the L-M design was up to 25% greater than that of a conventional cycle. This model was also used to calculate the performance of other pure refrigerants relative to that of dichlorodifluoromethane, R-12, in conventional and dual-loop RF designs. Projected efficiency gains for these cycles were more modest, ranging from 0 to 10%. Individual compressor calorimeter tests of nine combinations of evaporator and condenser temperatures usually used to map RF compressor performance were carried out with R-12 and two candidate L-M NARM's in several compressors. Several models of a commercially produced two-evaporator RF were obtained as test units. Two dual-loop RF designs were built and tested as part of this project. DOE

ON DEMAND, NON-HALON, FIRE EXTINGUISHING SYSTEMS Patent Application
Bengamin D. Smith, inventor (to Navy) 23 Jun. 1993 26 p
(AD-D015957; US-Patent-Appl-SN-083403; Navy-Case-75238) Avail: CASI HC A03/MF A01

A system and process for on-demand generation of inert, nonflammable gases and water vapor to decrease the available atmospheric oxygen in the ullage of a hydrocarbon fuel storage tank to a level that will not support combustion of the hydrocarbon fuel, is disclosed. One, or more, of a variety of non-Halon, fire suppressor charges are selectively contained in one or more gas generating cartridges. The gas generating cartridge(s), when activated, cause release of these charges to promote rapid chemical reactions and supply inert, nonflammable gases and water vapor to the tank ullage. Activation is accomplished in aircraft by, either pilot action or, by pressure and temperature sensors contained within the hydrocarbon fuel tank. DTIC

The work was directed towards developing a quantitative understanding of the phenomena that can enhance the heat and mass transfer in the absorber of an absorption chiller. Emphasis during the first year of a 3 year study was placed on compiling a comprehensive property data base and doing some exploratory experiments. During the second year experimental methods associated with heat and mass transfer in a falling film absorber were emphasized. All experiments used 2-ethyl-1-hexanal as the additive (surfactant) in an aqueous LiBr solution. The mass and heat transfer coefficients were found using the log mean averages based on the inlet and outlet properties. Significant accomplishments include: the onset of enhanced transfer was in the 2 to 200 ppm additive concentration range of surfactant and when 30 ppm was reached in the experiments the maximum enhancement was achieved. From 30 to 200 ppm additive concentration the enhancement remained the same. Visual observations of the experiments using the long absorber (85 cm) showed that chaotic flow was occurring only over the first half of the absorber. The majority of the tests were done with 100 ppm solutions of the surfactant. Tests as a function of absorber length showed that the mass transfer for 60% solution was about a factor of two. Tests on 50% LiBr showed an increase of a factor of 5.7 over the first 40 cm of length. NTIS

The complexity of space-based systems makes monitoring them and

diagnosing their faults taxing for human beings. Mission control operators are well-trained experts but they can not afford to have their attention diverted by extraneous information. During normal operating conditions monitoring the status of the components of a complex system alone is a big task. When a problem arises, immediate attention and quick resolution is mandatory. To aid humans in these endeavors we have developed an automated advisory system. Our advisory expert system, Trouble, incorporates the knowledge of the power system designers for Space Station Freedom. Trouble is designed to be a ground-based advisor for the mission controllers in the Control Center Complex at Johnson Space Center (JSC). It has been developed at NASA Lewis Research Center (LeRC) and tested in conjunction with prototype flight hardware contained in the Power Management and Distribution testbed and the Engineering Support Center, ESC, at LeRC. Our work will culminate with the adoption of these techniques by the mission controllers at JSC. This paper elucidates how we have captured power system failure knowledge, how we have built and tested our expert system, and what we believe are its potential uses. Author

DESIGN AND IMPLEMENTATION OF A STATUS AT A GLANCE USER INTERFACE FOR A POWER DISTRIBUTION EXPERT SYSTEM

Eugene M. Liberman (Sverdrup Technology, Inc., Brook Park, OH.), David B. Manner (Sverdrup Technology, Inc., Brook Park, OH.), James L. Dolce, and Pamela A. Mellor Dec. 1993 7 p Presented at the AIAA Computing in Aerospace 9, San Diego, CA, 19-21 Oct. 1993; sponsored by AIAA

(Contract NAS3-25266; RTOP 476-14-10)

(NASA-TM-106412; E-8248; NAS 1.15:106412; AIAA Paper 93-4657) Avail: CASI HC A02/MF A01

Expert systems are widely used in health monitoring and fault detection applications. One of the key features of an expert system is that it possesses a large body of knowledge about the application for which it was designed. When the user consults this knowledge base, it is essential that the expert system's reasoning process and its conclusions be as concise as possible. If, in addition, an expert system is part of a process monitoring system, the expert system's conclusions must be combined with current events of the process. Under these circumstances, it is difficult for a user to absorb and respond to all the available information. For example, a user can become distracted and confused if two or more unrelated devices in different parts of the system require attention. A human interface designed to integrate expert system diagnoses with process data and to focus the user's attention to the important matters provides a solution to the 'information overload' problem. This paper will discuss a user interface to the power distribution expert system for Space Station Freedom. The importance of features which simplify assessing system status and which minimize navigating through layers of information will be discussed. Design rationale and implementation choices will also be presented. Author

STATE-SPACE MODELS FOR MULTICHANNEL DETECTION Final Technical Report, Apr. 1993 - Jan. 1994

J. R. Roman and D. W. Davis Jul. 1993 138 p

(Contract F30602-92-C-0081)

(AD-A270608; SSC-TR-93-02; RL-TR-93-146) Avail: CASI HC A07/MF A02

In multichannel identification and detection (or model-based multichannel detection) problems the parameters of a model are identified from the observed channel process and the identified model is used to facilitate the detection of a signal in the observe process. A model-based multichannel detection algorithm was developed in the context of an innovations-based detection algorithm (IBDA) formulation for surveillance radar system applications. The state space model class was adopted to model the vector channel process because it is more general than the time series model class used in most analyses to date. An IBDA methodology was developed based on the canonical correlations algorithm which for state-space model identification offers performance advantages over alternative techniques. A computer simulation was developed to validate the methodology and the algorithm, and to carry out performance assessments. Simulation results indicate that the algorithm is capable of discriminating between the null hypothesis (clutter plus noise) and the alternative hypothesis (signal plus clutter plus noise). In summary, the applicability of the approach to radar system problems was established. DTIC

RADAR BACKSCATTER MEASUREMENTS FROM SIMULATED SEA ICE DURING CRRELEX 1990

S. G. Beaven, S. P. Gogineni, A. Gow (Army Cold Regions Research and Engineering Lab., Hanover, NH.), A. Lohanick (Army Cold Regions Research and Engineering Lab., Hanover, NH.), and K. Jezek (Ohio State Univ., Columbus.) Jun. 1993 135 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-89-J-1456)

(AD-A271034; RSL-TR-8243-2) Avail: CASI HC A07

Radar backscatter measurements were performed on artificially grown sea ice on an outdoor pond at the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) during the 1990 winter season. Measurements of microwave backscatter from simulated sea ice demonstrate that the dominant backscatter mechanism is the surface scatter. Both the co-polarized and cross-polarized measurements compare favorably with the predictions of surface scattering models at two frequencies. The surface parameters used in the models were measured directly from photographs of cross sections of the saline ice. Therefore, since two frequencies of backscatter measurements were predicted accurately by surface scatter models, the predominate backscatter must be from the surface. DTIC

PERSISTENT WAKEFIELDS ASSOCIATED WITH WAVEGUIDE DAMPING OF HIGHER ORDER MODES

N. M. Kroll and X. Lin Apr. 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993

(Contract DE-AC03-76SF-00515)

(DE93-040973; SLAC-PUB-6144; CONF-930511-429) Avail: CASI HC A01/MF A01

By means of an analytic model and numerical simulations, it was demonstrated that the wake of a waveguide damped cavity contains a persistent component which decays as t(sup -3/2) and thus is dominant at sufficiently large values of t. Because there are scenarios for which the effect gives rise to unacceptable beam instability, it cannot be ignored, but it seems likely that such an outcome can be avoided with proper design. DOE

MILLIMETER WAVE IMAGING TECHNOLOGY Final Report, 5 May 1989 - 4 May 1992

R. P. Smith, David Rutledge, and Neville Luhmann 6 Oct. 1993 9 p

(Contracts MIPR-137-91; MIPR-138-90)

(AD-A271257; ARO-27307.6-EL) Avail: CASI HC A02/MF A01

JPL/Caltech is pursuing millimeter-wave imaging technology for the Army Research Office because of the potential of penetrating smoke, fog, and darkness. During this reporting period, we made progress on varactor diode processing approaches appropriate for millimeter and submillimeter wave electronics, on fabricating and measuring diode grids for frequency multiplication and beam control, and especially in the area of grid amplifiers, which promise to deliver higher power at greatly reduced cost for millimeter-wave generation. STUDY OF ELECTROMAGNETIC WAVE SCATTERING FROM CHARACTERIZED ROUGH SURFACES Final Report, 20 Feb. 1990 - 30 Jun. 1993
Kevin A. ODonnell 4 Aug. 1993 80 p
(Contract DAAL03-90-G-0041)
(AD-A270931; ARO-27485.9-GS) Avail: CASI HC A05/MF A01

In our experimental and theoretical research during our ARO grant, we have studied the optical scattering properties of rough conducting surfaces that have structure comparable to or slightly greater than the illumination wavelength. We theoretically and experimentally studied the diffuse scatter for surfaces with one-dimensional roughness, where we have seen backscattering enhancement and strong polarization effects. In the angular correlation functions associated with the scattered light, we clearly see the coherent effects that give rise to backscattering enhancement. Further experimental studies have considered backscattering enhancement from a surface with two dimensional roughness, and we have theoretically investigated the effects of finite stylus width in the contact profilometer methods that we have used in our experiments. SPORADIC-E OBSERVATIONS DURING LoVHF TRANSIONOSPHERIC DIRECTION FINDER MEASUREMENTS
Robert B. Rose 1993 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A270619) Avail: CASI HC A02

A year long experimental program was conducted to measure refractive bending or how much the signal deviates from true line of sight, at low VHF (LoVHF) frequencies (29.5 MHz), and to determine whether this deviation or error could be predicted using large-scale ionospheric models such as the Ionospheric Conductivity and Electron Density (ICED) program. An experiment to directly measure the angle of arrival of a 29.5 MHz signal from an orbiting satellite was successfully completed. The satellite was in a circular orbit at an altitude of 1000 km. It was shown that refractive errors can be directly related to the electron density along the measurement slant range. The introduction of irregular patches of electron density occurring during sporadic-E events produced both horizontal and vertical gradients introducing large errors in both azimuth and elevation measurements. Nineteen test periods in May, June, July, and Aug. 1989 were affected by mid-latitude sporadic-E with the daytime E-region critical frequencies (foE's) reaching 13 MHz in one case. This paper will present examples of these effects. DTIC

GROUND WAVE EMERGENCY NETWORK. FINAL OPERATIONAL CAPABILITY. ENVIRONMENTAL ASSESSMENT FOR SOUTH CENTRAL MONTANA RELAY NODE, SITE NO. RN8C925MT
11 Feb. 1993 102 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A267795) Avail: CASI HC A06

The Ground Wave Emergency Network (GWEN) is a radio communication system designed to relay emergency messages between strategic military areas in the continental United States. The proposed action covered by this Environmental Assessment (EA) includes construction and operation of a relay node of the GWEN in south central Montana. This relay node will provide essential connections with adjacent nodes in the network. The major features of a GWEN relay node and associated environmental impacts common to all sites are addressed in the Final Environmental Impact Statement (FEIS) for the Final Operational Capability (FOC) phase of GWEN. This EA is tiered from that FEIS and addresses site-specific conditions at the candidate GWEN sites (CGS's) for this particular site search area.

ROBUST, HIGH-SPEED NETWORK DESIGN FOR LARGE-SCALE MULTIPROCESSING
Andre DeHon Sep. 1993 219 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1698)
(AD-A271003; AI-TR-1445) Avail: CASI HC A10

Large-scale multiprocessing remains an elusive, yet promising, paradigm for achieving high-performance computation. As machine size scales upward, there are two important aspects of multiprocessor systems which will generally get worse rather than better: (1) interprocessor communication latency will increase; and (2) the probability that some component in the system will fail will increase. Both of these problems can prevent us from realizing the potential benefits of large-scale multiprocessing. In this document we consider the problem of designing networks which simultaneously minimize communication latency while maximizing fault tolerance for large-scale multiprocessors. Using a synergy of techniques including connection topologies, routing protocols, signalling techniques, and packaging technologies, we assemble integrated, system-level solutions to this network design problem. In particular, we recommend the use of the following: multipath, multistage networks; simple, source-responsible routing protocols; stochastic fault-avoidance; dense three-dimensional packaging; low-voltage, series-terminated transmission line signalling; and scan based diagnostics and reconfiguration. AN EXTENDED UTD ANALYSIS FOR THE SCATTERING AND DIFFRACTION FROM CUBIC POLYNOMIAL STRIPS Final Report
E. D. Constantinides and R. J. Marhefka Jan. 1993 54 p
(Grant NsG-1498)
(NASA-CR-194581; NAS 1.26:194581; Rept-725311-2) Avail: CASI HC A04/MF A01

Spline and polynomial type surfaces are commonly used in high frequency modeling of complex structures such as aircraft, ships, reflectors, etc. It is therefore of interest to develop an efficient and accurate solution to describe the scattered fields from such surfaces. An extended Uniform Geometrical Theory of Diffraction (UTD) solution for the scattering and diffraction from perfectly conducting cubic polynomial strips is derived and involves the incomplete Airy integrals as canonical functions. This new solution is universal in nature and can be used to effectively describe the scattered fields from flat, strictly concave or convex, and concave convex boundaries containing edges. The classic UTD solution fails to describe the more complicated field behavior associated with higher order phase catastrophes and therefore a new set of uniform reflection and first-order edge diffraction coefficients is derived. Also, an additional diffraction coefficient associated with a zero-curvature (inflection) point is presented. Higher order effects such as double edge diffraction, creeping waves, and whispering gallery modes are not examined. The extended UTD solution is independent of the scatterer size and also provides useful physical insight into the various scattering and diffraction processes. Its accuracy is confirmed via comparison with some reference moment method results.

A COMPARATIVE STUDY OF AN ABC AND AN ARTIFICIAL ABSORBER FOR TRUNCATING FINITE ELEMENT MESHES
T. Oezdemir and John L. Volakis Dec. 1993 16 p
(Contract NCA2-839)
(NASA-CR-194275; NAS 1.26:194275; UMICH-031173-1-T) Avail: CASI HC A03/MF A01

The type of mesh termination used in the context of finite element formulations plays a major role on the efficiency and accuracy of the field solution. The performance of an absorbing boundary condition (ABC) and an artificial absorber (a new concept) for terminating the finite element mesh was evaluated. This analysis is done in connection with the problem of scattering by a finite slot array in a thick ground plane. The two approximate mesh truncation schemes are compared with the exact finite element-boundary integral (FEM-BI) method in terms of accuracy and efficiency. It is demonstrated that both approximate truncation schemes yield reasonably accurate results even when the mesh is extended only 0.3 wavelengths away from the array aperture. However, the artificial absorber termination method leads to a substantially more efficient solution. Moreover, it is shown that the FEM-BI method remains quite competitive with the FEM-artificial absorber method when the FFT is used for computing the matrix-vector products in the iterative solution algorithm. These conclusions are indeed surprising and of major importance in electromagnetic simulations based on the finite element method. Author (revised)

TARGET MOTION DETECTING IMPULSE DOPPLER RADAR SYSTEM Patent
Robert E. Jehle, inventor (to Navy) and David F. Hudson, inventor (to Navy) 15 Jun. 1993 7 p Filed 25 Mar. 1992
(AD-D015898; US-Patent-5,220,328; US-Patent-Appl-SN-857536; US-Patent-Class-342-21) Avail: US Patent and Trademark Office

Radiant energy intermittently emitted from a transmitter is reflected as echo pulses from a moving target being interrogated to produce Doppler signals by counting of photons of the echo pulses during time domain intervals between emission from the transmitter. Such counting of photons is limited to the time domain intervals by operational control of a laser pump through which a reference beam is generated at an energy level activating detectors irradiated by such beam to count the photons absorbed therein after capture or the photons by a receiving antenna. NEW ALGORITHM OF GROUND TRACK PROCESSING IN HIGH-FREQUENCY SKYWAVE OVER-THE-HORIZON-B RADAR
Jiao Peinan 6 Aug. 1993 19 p Transl. into ENGLISH from Dianzi Xuebao (China), v. 19, no. 1, 1991 p 1-6
(AD-A267821; FASTC-ID(RS)T-0853-92) Avail: CASI HC A03/MF A01

In this paper, the concept pattern of the recognition tracking coordinate transformation data processor in HF skywave OTH-B radar is described. A new algorithm to determine the ground distance of a moving object from the time delay transformation of HF radar is proposed. Just the probe data obtained from only a single radar station are needed; there is no need to know the midpoint ionospheric data. The calculated ground track is compared with the actual track and the results show that the mean deviation is less than four percent. DTIC

Motivated by the goal of efficient, effective, high-speed integrated-circuit realization, we have discovered an algorithm for high speed Fourier analysis called the Arithmetic Fourier Transform (AFT). It is based on the number-theoretic method of Mobius inversion, a method that is well suited for integrated-circuit realization. The computation of the AFT can be carried out in parallel, pipelined channels, and the individual operations are very simple to execute and control. Except for a single scaling in each channel, all the operations are additions or subtractions. Thus, it can reduce the required power, volume, and cost. Also, analog switched-capacitor realizations of the AFT have been studied. We have also analyzed the performance of a broad and useful class of data adaptive signal estimation algorithms. This in turn has led to our proposed improvements in the methods. We have used perturbation analysis of the rank-reduced data matrix to calculate its statistical properties. The improvements made have been demonstrated by computer simulation as well as by comparison with the Cramer-Rao Bound. DTIC

A PHYSICAL OPTICS/EQUIVALENT CURRENTS MODEL FOR THE RCS OF TRIHEDRAL CORNER REFLECTORS
Constantine A. Balanis and Anastasis C. Polycarpou *In its* RCS Analysis of Plate Geometries, Parts 1 and 2 31 Jul. 1993 p 22-41 (For primary document see N94-20269 05-32)
Avail: CASI HC A03/MF A01

The scattering in the interior regions of both square and triangular trihedral corner reflectors is examined. The theoretical model presented combines geometrical and physical optics (GO and PO), used to account for reflection terms, with equivalent edge currents (EEC), used to account for first-order diffractions from the edges. First-order, second-order, and third-order reflection terms are included. Calculating the first-order reflection terms involves integrating over the entire surface of the illuminated plate. Calculating the second- and third-order reflection terms, however, is much more difficult because the illuminated area is an arbitrary polygon whose shape is dependent upon the incident angles. The method for determining the area of integration is detailed. Extensive comparisons between the high-frequency model, Finite-Difference Time-Domain (FDTD) and experimental data are used for validation of the radar cross section (RCS) of both square and triangular trihedral reflectors. CHARACTERIZATION OF ELECTROMAGNETIC FIELDS IN AN EXTENDED CHAMBER AT THE SHORT PULSE EXPERIMENTAL ELECTRON DEVICE (SPEED) SIMULATOR Final Report, May - Dec. 1992
Kenneth K. Hunt Apr. 1993 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F29601-89-C-0014)
(AD-A265955; PL-TR-92-1065; AD-E201456) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The electromagnetic (EM) fields present during testing in a large vacuum chamber at the Short Pulse Experimental Electron Device (SPEED) facility are observed and measured using B-dot and D-dot detectors. Because the cathode of the vacuum diode is exposed to the chamber, the EM fields are significant and could adversely affect nonfaraday-shielded experiments. The differential magnetic fields and electric fields are nearly isotopically distributed, build to a maximum at 100 - 200 ns of 7.9 x 10(exp 9) A/m-s and 9 x 10(exp 10) V/m-s, respectively, then decay for approximately 1000 ns. Fourier analysis of spectra gives primary frequencies (460, 550, and 60 MHz) characteristic of the dimensions of the chamber and of electrons rebounding between the target and the pulse generators. A collimated damper is designed which should eliminate most EM fields in future tests in this configuration. DTIC

An electromagnetic field sensor apparatus which measures the amplitude, phase, frequency and polarization of an incoming electromagnetic field as well as the angle of arrival of an incident electromagnetic field is introduced. A Luneberg lens focuses an incoming electromagnetic wave entering on one side of the Luneberg lens onto a point on the opposite side of the lens. A pair of photonic sensor which may be electro-optic modulators or Pockel cells are positioned on the Luneberg lens at the point upon which the incident electromagnetic wave is focused. The sensing axis of one of the electro-optic modulators is perpendicular to the sensing axis of the other electro-optic modulator. Polarized light is provided to each photonic sensor along an optical path which passes through the sensor. Each photonic sensor modulates the polarized light passing therethrough when the photonic sensor detects the incident electromagnetic wave. DTIC

PROBE COMPENSATION IN CYLINDRICAL NEAR-FIELD SCANNING: A NOVEL SIMULATION METHODOLOGY Abstract Only
Ziad A. Hussein and Yahya Rahmat-Samii *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 21 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

Probe pattern compensation is essential in near-field scanning geometry, where there is a great need to accurately know far-field patterns at wide angular range. This paper focuses on a novel formulation and computer simulation to determine the precise need for and effect of probe compensation in cylindrical near-field scanning. The methodology is applied to a linear test array antenna and the NASA scatterometer radar antenna. The formulation is based on representing the probe by its equivalent tangential magnetic currents. The interaction between the probe equivalent aperture currents and the test antenna fields is obtained with the application of a reciprocity theorem. This allows us to obtain the probe vector output pickup integral which is proportional to the amplitude and phase of the electric field induced in the probe aperture with respect to its position to the test antenna. The integral is evaluated for each probe position on the required sampling point on a cylindrical near-field surface enclosing the antenna. The use of a hypothetical circular-aperture probe with a different radius permits us to derive closed-form expressions for its far-field radiation patterns. These results, together with the probe vector output pickup, allow us to perform computer simulated synthetic measurements. The far-field patterns of the test antenna are formulated based on cylindrical wave expansions of both the probe and test antenna fields. In the limit as the probe radius becomes very small, the probe vector output is the direct response of the near-field at a point, and no probe compensation is needed. Useful results are generated to compare the far-field pattern of the test antenna constructed from the knowledge of the simulated near-field with and without probe pattern compensation and the exact results. These results are important since they clearly illustrate the angular range over which probe compensation is needed. It has been found that a probe with an aperture radius of 0.25(lambda), 0.5(lambda), and 1(lambda) needs a little probe compensation, if any, near the test antenna main beam. In addition, a probe with low directivity may provide a better signal-to-noise ratio than a highly directive one. This is evident in test antenna patterns without probe compensation at wide angles. ANALYSIS OF MICROSTRIP DIPOLES AND SLOTS TRANSVERSELY COUPLED TO A MICROSTRIP LINE USING THE FDTD METHOD Abstract Only
A. N. Tulintseff *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 32 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

Printed dipole elements and their complement, linear slots, are elementary radiators that have found use in low-profile antenna arrays. Low-profile antenna arrays, in addition to their small size and low weight characteristics, offer the potential advantage of low-cost, high-volume production with easy integration with active integrated circuit components. The design of such arrays requires that the radiation and impedance characteristics of the radiating elements be known. The FDTD (Finite-Difference Time-Domain) method is a general, straight-forward implementation of Maxwell's equations and offers a relatively simple way of analyzing both printed dipole and slot elements. Investigated in this work is the application of the FDTD method to the analysis of printed dipole and slot elements transversely coupled to an infinite transmission line in a multilayered configuration. Such dipole and slot elements may be used in dipole and slot series-fed-type linear arrays, where element offsets and interelement line lengths are used to obtain the desired amplitude distribution and beam direction, respectively. The design of such arrays is achieved using transmission line theory with equivalent circuit models for the radiating elements. In an equivalent circuit model, the dipole represents a shunt impedance to the transmission line, where the impedance is a function of dipole offset, length, and width. Similarly, the slot represents a series impedance to the transmission line. The FDTD method is applied to single dipole and slot elements transversely coupled to an infinite microstrip line using a fixed rectangular grid with Mur's second order absorbing boundary conditions. Frequency-dependent circuit and scattering parameters

are obtained by saving desired time-domain quantities and using the Fourier transform. A Gaussian pulse excitation is applied to the microstrip transmission line, where the resulting reflected signal due to the presence of the radiating element is used to determine the equivalent element impedance. FD-TD MODELING OF 2-D DIELECTRIC WAVEGUIDES FOR PROPAGATION AND SCATTERING OF FEMTOSECOND OPTICAL SOLITONS Abstract Only

Rose Joseph (Northwestern Univ., Evanston, IL.), Peter Goorjian, and Allen Taflove (Northwestern Univ., Evanston, IL.) *In* JPL, Progress In Electromagnetics Research Symposium (PIERS) 1993 p 35 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Experimentalists have produced all-optical switches capable of 100-fs responses. To adequately model such switches, nonlinear effects in optical materials (both instantaneous and dispersive) must be included. In principle, the behavior of electromagnetic fields in nonlinear dielectrics can be determined by solving Maxwell's equations subject to the assumption that the electric polarization has a nonlinear relation to the electric field. However, until our previous work, the resulting nonlinear Maxwell's equations have not been solved directly. Rather, approximations have been made that result in a class of generalized nonlinear Schrodinger equations (GNLSE) that solve only for the envelope of the optical pulses. In this paper, we present first-time calculations from the vector nonlinear Maxwell's equations of femtosecond soliton propagation and scattering, including carrier waves, in two-dimensional systems of dielectric waveguides exhibiting the Kerr and Raman quantum effects. We use the finite-difference time-domain (FD-TD) method in an extension of our 1-D work. There, in a fundamental innovation, we treated the linear and nonlinear convolutions for the electric polarization as new dependent variables. By differentiating these convolutions in the time domain, we derived an equivalent system of coupled, nonlinear second-order ODE's. These equations together with Maxwell's equations form the system that is solved to determine the electromagnetic fields in inhomogeneous nonlinear dispersive media. Backstorage in time is limited to only that needed by the time-integration algorithm for the ODE's, rather than that needed to store the time-history of the kernel functions of the convolutions (1000-10,000 time steps). Thus, a 2-D nonlinear optics model from Maxwell's equations is now feasible. Author (revised)

A GENERAL ROUGH-SURFACE INVERSION ALGORITHM: THEORY AND APPLICATION TO SAR DATA Abstract Only

M. Moghaddam *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 66 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Rough-surface inversion has significant applications in interpretation of SAR data obtained over bare soil surfaces and agricultural lands. Due to the sparsity of data and the large pixel size in SAR applications, it is not feasible to carry out inversions based on numerical scattering models. The alternative is to use parameter estimation techniques based on approximate analytical or empirical models. Hence, there are two issues to be addressed, namely, what model to choose and what estimation algorithm to apply. Here, a small perturbation model (SPM) is used to express the backscattering coefficients of the rough surface in terms of three surface parameters. The algorithm used to estimate these parameters is based on a nonlinear least-squares criterion. The least-squares optimization methods are widely used in estimation theory, but the distinguishing factor for SAR applications is incorporating the stochastic nature of both the unknown parameters and the data into formulation, which will be discussed in detail. The algorithm is tested with synthetic data, and several Newton-type least-squares minimization methods are discussed to compare their convergence characteristics. Finally, the algorithm is applied to multifrequency polarimetric SAR data obtained over some bare soil and agricultural fields. Results will be shown and compared to ground-truth measurements obtained from these areas. The strength of this general approach to inversion of SAR data is that it can be easily modified for use with any scattering model without changing any of the inversion steps. Note also that, for the same reason it is not limited to inversion of rough surfaces, and can be applied to any parameterized scattering process. Author (revised)

VARIABLE-PERMITTIVITY LINEAR INVERSE PROBLEM FOR THE H(SUB z)-POLARIZED CASE Abstract Only

M. Moghaddam and W. C. Chew (Illinois Univ., Urbana-Champaign.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 77 (For primary document see N94-20403 05-32)

The H(sub z)-polarized inverse problem has rarely been studied before due to the complicated way in which the unknown permittivity appears in the wave equation. This problem is equivalent to the acoustic inverse problem with variable density. We have recently reported the solution to the nonlinear variable-permittivity H(sub z)-polarized inverse problem using the Born iterative method. Here, the linear inverse problem is solved for permittivity (epsilon) and permeability (mu) using a different approach which is an extension of the basic ideas of diffraction tomography (DT). The key to solving this problem is to utilize frequency diversity to obtain the required independent measurements. The receivers are assumed to be in the far field of the object, and plane wave incidence is also assumed. It is assumed that the scatterer is weak, so that the Born approximation can be used to arrive at a relationship between the measured pressure field and two terms related to the spatial Fourier transform of the two unknowns, epsilon and mu. The term involving permeability corresponds to monopole scattering and that for permittivity to dipole scattering. Measurements at several frequencies are used and a least squares problem is solved to reconstruct epsilon and mu. It is observed that the low spatial frequencies in the spectra of epsilon and mu produce inaccuracies in the results. Hence, a regularization method is devised to remove this problem. Several results are shown. Low contrast objects for which the above analysis holds are used to show that good reconstructions are obtained for both permittivity and permeability after regularization is applied. The importance of collecting high quality ground truth before a SAR mission over a forested area is two fold. First, the ground truth is used in the analysis and interpretation of the measured backscattering properties; second, it helps to justify the use of a scattering model to fit the measurements. Unfortunately, ground truth is often collected based on visual assessment of what is perceived to be important without regard to the mission itself. Sites are selected based on brief surveys of large areas, and the ground truth is collected by a process of selecting and grouping different scatterers. After the fact, it may turn out that some of the relevant parameters are missing. A three-layer canopy model based on the radiative transfer equations is used to determine, before hand, the relevant parameters to be collected. Detailed analysis of the contribution to scattering and attenuation of various forest components is carried out. The goal is to identify the forest parameters which most influence the backscattering as a function of frequency (P-, L-, and C-bands) and incident angle. The influence on backscattering and attenuation of branch diameters, lengths, angular distribution, and permittivity; trunk diameters, lengths, and permittivity; and needle sizes, their angular distribution, and permittivity are studied in order to maximize the efficiency of the ground truth collection efforts. Preliminary results indicate that while a scatterer may not contribute to the total backscattering, its contribution to attenuation may be significant depending on the frequency. Author

MODIFICATIONS TO THE THREE-COMPONENT CLASSIFICATION ALGORITHM FOR SAR DATA Abstract Only

M. Moghaddam and A. Freeman *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 164 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Previously, a scattering model was used to classify SAR data as due

to three mechanisms: surface or odd-bounce scattering; double-bounce scattering; and volume scattering. A Bragg rough-surface model was used for odd-bounce scattering, and two reflecting surfaces, as in a dihedral corner reflector, represented the double-bounce scattering mechanism. A random collection of infinitely thin cylinders was used to model the volume scattering contribution. It was assumed that the cylinders are uniformly oriented in all directions. In this work, modifications are made to the above model, which include specifying a preferred orientation for the cylinders representing branches and using thin cylinders of finite thickness as opposed to infinitely thin ones. In the first case, the preferred orientation is represented by a probability density function in the form of a dirac delta function. For the second case, small argument asymptotic expansions of Bessel functions are used to express the volume scattering contributions in terms of quantities containing the average radius of the cylinders. Since in each case the number of unknowns exceeds that of equations, simplifying assumptions are made. The solutions are applied to multifrequency polarimetric SAR data to obtain the new unknowns in addition to the relative contributions of each scattering mechanism. Several results are presented. It is found that the calculated percentage of each mechanism does not change significantly compared to the original model; however, additional information is gained about the scatterers. Noise equivalent sigma(sup 0) is a fundamental parameter in any synthetic aperture radar (SAR) measurement. Knowledge of the noise equivalent sigma(sup 0) allows the radar application scientist to band the error contributions due to noise present in his/her data. In this paper, a novel technique for determining noise equivalent sigma(sup 0) is presented. It has been observed that a pair of images obtained by a SAR over the same area in a nearly repeating orbit can demonstrate a high degree of correlation, depending on the baseline. If noise independence and signal power invariance are assumed, an estimate for the noise equivalent sigma(sup 0) for each image can be determined without any known ground targets. We examine the application of this technique to several images of different backscatter obtained by ERS-1. Author (revised)

Calculation of accurate vector winds from scatterometers requires knowledge of the relationship between backscatter cross-section and the geophysical variable of interest. As the detailed dynamics of wind generation of centimetric waves and radar-sea surface scattering at moderate incidence angles are not well known, empirical scatterometer model functions relating backscatter to winds must be developed. Less well appreciated is the fact that, given an accurate model function and some knowledge of the dominant scattering mechanisms, significant information on the amplitudes and directional distributions of centimetric roughness elements on the sea surface can be inferred. accurate scatterometer model functions can thus be used to investigate wind generation of short waves under realistic conditions. The present investigation involves developing an empirical model function for the C-band (5.3 GHz) ERS-1 scatterometer and comparing Ku-band model functions with the C-band model to infer information on the two-dimensional spectrum of centimetric roughness elements in the ocean. The C-band model function development is based on collocations of global backscatter measurements with operational surface analyses produced by meteorological agencies. Strengths and limitations of the method are discussed, and the resulting model function is validated in part through comparison with the actual distributions of backscatter cross-section triplets. Details of the directional modulation as well as the wind speed sensitivity at C-band are investigated. Analysis of persistent outliers in the data is used to infer the magnitudes of non-wind effects (such as atmospheric stratification, swell, etc.). The ERS-1 C-band instrument and the Seasat Ku-band (14.6 GHz) scatterometer both imaged waves of approximately 3.4 cm wavelength assuming that Bragg scattering is the dominant mechanism. Comparisons of the C-band and Ku-band model functions are used both to test the validity of the postulated Bragg mechanism and to investigate the directional distribution of the imaged waves under a variety of conditions where Bragg scatter is dominant. Ku-BAND OCEAN RADAR BACKSCATTER OBSERVATIONS DURING SWADE Abstract Only **c43**
S. V. Nghiem, F. K. Li, S. H. Lou, and G. Neumann *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 188 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

We present results obtained by an airborne Ku-band scatterometer during the Surface Wave Dynamics Experiment (SWADE). The specific objective of this study is to improve our understanding of the relationship between ocean radar backscatter and near surface winds. The airborne scatterometer, NUSCAT, was flown on the NASA Ames C-130 over an instrumented oceanic area near 37 deg N and 74 deg W. A total of 10 flights from 27 Feb. to 9 Mar. 1991 were conducted. Radar backscatter at incidence angles of 0 to 60 deg were obtained. For each incidence angle, the NUSCAT antenna was azimuthally scanned in multiple complete circles to measure the azimuthal backscatter modulations. Both horizontal and vertical polarization backscatter measurements were made. In some of the flights, the cross-polarization backscatter was measured as well. Internal calibrations were carried out throughout each of the flights. Preliminary results indicate that the radar was stable to +/-0.3 dB for each flight. In this paper, we present studies of the backscatter measurements over several crossings of the Gulf Stream. In these crossings, large air-sea temperature differences were encountered and substantial changes in the radar cross section were observed. We summarize the observations and compare them to the changes of several wind variables across the Gulf Stream boundary. In one of the flights, the apparent wind near the cold side of the Gulf Stream was very low (less than 3 m/s). The behavior of the radar cross sections at such low wind speeds and a comparison with models are presented. A case study of the effects of swell on the absolute cross section and the azimuthal modulation pattern is presented. Significant wave heights larger than m were observed during SWADE. The experimentally observed effects of the swell on the radar backscatter are discussed. The effects are used to assess the uncertainties in wind retrieval due to underlying waves. A summary of azimuthal modulation from our ten-flight of NUSCAT data is given. Wind velocities, air and sea surface temperature, ocean spectrum, and other variables measured from aircraft and buoys are also shown. Author (revised)

This study is using airborne Ku-band data to address questions which have implications for both model function development and for advancing our physical understanding of the sea surface. Concurrent measurements of ocean directional spectra, significant wave height, and mean surface roughness are made using the capabilities of the radar ocean wave spectrometer (ROWS). The NASA/GSFC's ROWS is a 15 GHz pulse compressed radar which is a radar sensor designed to measure the direction of the long wave components using spectral analysis of the tilt induced reflectively modulation. The ROWS are modified to cycle at 50 Hz for the scanning spectrometer antenna and a wide beamwidth nadir altimeter mode. This change allows the sensor to simultaneously measure directional wave spectra, wave height, mean square slope parameter, and small scale surface roughness. The surface stress caused by the wind is widely believed to be the predominant quantity related to the Ku-band radar cross section for a wide range of incidence angles. The complete coverage in the quasi specular

region provided by one sensor is essential to understand the uncertainties between the scattering model and what is happening on the surface. For this presentation, special attention is devoted to sort out some measurement of the anisotropy associated with the band of high frequencies. Using the other geophysical parameters, comparisons are then made with the classic spectral form currentlyused to describe the wind impact on the sea surface. Author (revised)

Recently, it has been observed that the brightness temperatures of sea surfaces correlate with the azimuth angle of the ocean wind vector, indicating that ocean wind direction can not only be retrieved from the microwave backscatter, but also from the brightness temperature measurements. In this paper, comparison of the theoretical result calculated from a two-scale emission and scattering model with the Seasat and SSM/I model functions and aircraft measurements is presented and potential applications of microwave polarimetry are discussed. In our two-scale model, the modified reflectivities of large scale surfaces are calculated by extending the small perturbation method to the second order for small scale perturbation with anisotropic directional spectrum. It was found that the modified reflectivities derived from the second-order scattered field agree excellently well with the results obtained from a Monte Carlo simulation technique which numerically calculates the polarimetric reflectivities of one-dimensional random rough surfaces with a power-law spectrum. Without the second-order correction, the modified reflectivities of the rough surfaces are significantly over-estimated and sign errors are observed in the third and fourth Stokes parameters for thermal emissions. The surface spectrum parameters and two-scale cutoff are selected so that the calculated scattering and emission signatures agree with the reported model functions for Seasat and SSM/I. Subsequently, the polarimetric signatures of sea surfaces are illustrated to indicate the possibility of reducing the number of azimuthal looks required for spaceborne sensors in the remote sensing of ocean wind by using the polarimetric information. Furthermore, it is found that contrary to the dependence of backscattering coefficients on incidence angles, polarimetric brightness temperatures display a stronger wind direction dependence in the near nadir-looking direction than away from nadir. Finally, we discuss the potential of a single-look polarimetric radiometer for wind retrieval. Author

Calculations of light scattering by small particles are important in many diverse fields of science and engineering. In many cases of practical interest, scattering particles are nonspherical and are distributed over sizes and orientations. However, accurate light scattering computations for ensembles of nonspherical particles are difficult and time-consuming, and the literature in which such calculations are reported is rather scarce. In this paper, the T-matrix approach, as extended recently to randomly oriented particles, is used to calculate rigorously light scattering by size distributions of randomly oriented axially symmetric particles. To model the variation of particle sizes in real ensembles, we use a power law distribution typical of some terrestrial aerosols. Contour plots of intensity and degree of linear polarization for polydisperse prolate and oblate spheroids of different aspect ratios and effective equivalent-sphere size parameters from 0 to 10 are calculated and compared with calculations for equivalent spheres. The angular scattering behavior of nonspherical polydispersions is found to be greatly different from that of spheres, while the scattering properties of oblate and prolate spheroids of the same aspect ratio are similar. With increasing particle size, both intensity and polarization become more shape-dependent. In general, nonspherical particles are stronger side scatterers and weaker backscatterers than equivalent spheres. With increasing aspect ratio of nonspherical particles polarization tends to be predominantly positive. Possible effects of particle nonsphericity on optical remote sensing of atmospheric aerosols are discussed. Author

Terrain height variations in mountainous areas cause two problems in the radiometric correction of SAR images: the first being that the wrong elevation angle may be used in correcting for the radiometric variation of the antenna pattern; the second that the local incidence angle used in correcting the projection of the pixel area from slant range to ground range coordinates may vary from that given by the flat earth assumption. We propose a novel design of a SAR system which exploits the monopulse principle to determine the elevation angle and thus the height at the different parts of the image. The key element of such a phase monopulse system is an antenna, which can be divided into a lower and upper half in elevation using a monopulse comparator. In addition to the usual sum pattern, the elevation difference pattern can be generated by a -pi phase shift on one half of the antenna. From the ratios of images radiometrically modulated by the difference and sum antenna pattern in cross-track direction, we can derive the appropriate elevation angle at any point in the image. Together with the slant range we can calculate the height of the platform above this point using information on the antenna pointing and the platform attitude. This operation, repeated at many locations throughout the image, allows us to build up a topographic map of the height of the aircraft above each location. Inversion of this map, using the precisely determined aircraft altitude and the accurate flight path, leads to the actual topography of the imaged surface. The precise elevation of one point in the image could also be used to convert the height map to a topographic map. In this paper, we present design considerations for a corresponding airborne SAR system in X-Band and give estimates of the error due to system noise and azimuth ambiguities as well as the expected performance and precision in topographic mapping. Low-altitude wind shear has been identified by several aviation interests as a significant hazard to the safety of flying. The hazard may be greatest when the wind shear is due to an unpredicted and short-lived microburst occurring in the immediate flight path of an aircraft during takeoff or landing. Researchers from the NASA Langley Research Center have investigated wind shear by developing a suite of remote sensing instruments and then using these instruments in an airborne wind shear detection flight program. Among these instruments were a Doppler radar, a lidar, and an infrared sensor; these were supported by in situ measurements of aircraft and environmental parameters and by ground-based Doppler radars. The basic problem addressed was the airborne detection and measurement of meteorologically-induced wind shear sufficiently ahead of the aircraft to allow avoidance. If the remote measurements of the shear and its associated radar reflectivity did not exceed set limits, the airplane then continued through the wind shear so that in situ measurements could be made for comparison. Initial detection and vectoring to the wind shear was normally given from a ground-based Doppler weather radar and most of the wind shear events were due to microbursts, both wet and dry. This paper considers the problems of sampling the wind shear event, time and space

registration among the various sensors, coordination of the various sensors' beams and sampling volumes, and also various techniques for portraying the data, both for research and for presentation. Examples are given based on data from the 1991 and 1992 NASA/FAA wind shear flights, and the results and conclusions are generalized to other flight experiments involving multi-sensor electromagnetic data sets. An airborne, forward-looking, pulse, Doppler radar has been developed in conjunction with the joint FAA/NASA Wind Shear Program. This radar represents a first in an emerging technology. The radar was developed to assess the applicability of an airborne radar to detect low altitude hazardous wind shears for civil aviation applications. Such a radar must be capable of looking down into the ground clutter environment and extracting wind estimates from relatively low reflectivity weather targets. These weather targets often have reflectivities several orders of magnitude lower than the surrounding ground clutter. The NASA radar design incorporates numerous technological and engineering achievements in order to accomplish this task. The basic R/T unit evolved from a standard Collins 708 weather radar, which supports specific pulse widths of 1-7 microns and Pulse Repetition Frequencies (PRF) of less than 1-10 kHz. It was modified to allow for the output of the first IF signal, which fed a NASA developed receiver/detector subsystem. The NASA receiver incorporated a distributed, high-speed digital attenuator, producing a range bin to range bin automatic gain control system with 65 dB of dynamic range. Using group speed information supplied by the aircraft's navigation system, the radar signal is frequency demodulated back to base band (zero Doppler relative to stationary ground). The In-phase & Quadrature-phase (I/Q) components of the measured voltage signal are then digitized by a 12-bit A-D converter (producing an additional 36 dB of dynamic range). The raw I/Q signal for each range bin is then recorded (along with the current radar & aircraft state parameters) by a high-speed Kodak tape recorder. Author

CLASSIFICATION OF SIMPLE VEGETATION TYPES USING POLSAR IMAGE DATA Abstract Only **c43**
A. Freeman *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 387 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

Mapping basic vegetation or land cover types is a fairly common problem in remote sensing. Knowledge of the land cover type is a key input to algorithms which estimate geophysical parameters, such as soil moisture, surface roughness, leaf area index or biomass from remotely sensed data. In an earlier paper, an algorithm for fitting a simple three-component scattering model to POLSAR data was presented. The algorithm yielded estimates for surface scatter, double-bounce scatter and volume scatter for each pixel in a POLSAR image data set. In this paper, we show how the relative levels of each of the three components can be used as inputs to simple classifier for vegetation type. Vegetation classes include no vegetation cover (e.g. bare soil or desert), low vegetation cover (e.g. grassland), moderate vegetation cover (e.g. fully developed crops), forest and urban areas. Implementation of the approach requires estimates for the three components from all three frequencies available using the NASA/JPL AIRSAR, i.e. C-, L- and P-bands. The research described in this paper was carried out by the Jet Propulsion Laboratory, California Institute of Technology under a contract with the National Aeronautics and Space Administration. Two types of C-band aircraft interferometric Synthetic Aperture Radar (SAR) are being developed at JPL to measure the ocean wave characteristics. Each type requires two identical antennas with each having a long rectangular aperture to radiate fan-shaped beam(s). One type of these radars requires each of its antennas to radiate a broadside beam that will measure the target's cross-track velocity. The other type, having each of its antennas to radiate two off-broadside pointed beams, will allow the measurement of both the cross-track and the along-track velocities of the target. Because flush mounting of the antenna on the aircraft fuselage is desirable, microstrip patch array is selected for these interferometric SAR antennas. To meet the radar system requirement, each array needs a total of 76 microstrip patches which are arranged in a 38 x 2 rectangular aperture with a physical size of 1.6m x 16.5cm. To minimize the insertion loss and physical real estate of this relatively long array, a combined series/parallel feed technique is used. Techniques to suppress cross-pol radiation and to effectively utilize the RF power are also implemented. Cross-pol level of lower than -30 dB from the co-pol peak and low insertion loss of 0.36 dB have been achieved for both types of arrays. For the type of radar that requires two off-broadside pointed beams, a simple phasing technique is used to achieve this dual-beam capability with adequate antenna gain (20 dBi) and sidelobe level (-14 dB). Both radar arrays have been flight tested on aircraft with excellent antenna performance demonstrated. Author

This paper will report two recent R&D efforts in printed antennas at NASA Lewis Research Center. These efforts are: (1) to enhance the current antenna performance in gain, bandwidth and pattern characteristics, and (2) to develop coplanar waveguide/aperture coupled feeding technique for dual excitation of a patch antenna. Research in area (1) has led to the development of a nonplanar linearly tapered slot antenna (LTSA) which has exhibited over 10 dB gain with broad bandwidth and excellent radiation patterns. This endfire antenna element is most suitable for use in MMIC arrays of 'brick' construction. A space power amplifier composed of active LTSA has been demonstrated and shown to have a gain of 30 dB at 20 GHz. In each of the antenna elements, a GaAs monolithic microwave integrated circuit (MMIC) three-stage power amplifier is integrated with two LTSA's. A single active LTSA has also been demonstrated and exhibited a power gain of 6.7 dB with the MMIC amplifier turned on. The aperture coupled feeding technique with coplanar waveguide feeds has demonstrated high coupling efficiency on both LTSA and patch antennas. Recent efforts have been focused on applying this technique for dual excitation (dual frequency and/or dual polarization) of a patch antenna. Preliminary results confirm the feasibility of this approach. Further development is required to improve the coupling efficiency and antenna radiation characteristics. Author

Recently an approach which combines the finite element technique and an integral equation to determine the fields scattered by inhomogeneous bodies of complicated shape has been proposed. Basically, a mathematical surface which encloses the scatterers is introduced, thus dividing the space into an interior and an exterior volume, in which the finite element technique and an integral equation for EM scattering, respectively, are applied. The integral equation is set up for the tangential components of the fields at the surface, while the interior volume the unknowns are the total fields. Continuity of the tangential fields at the boundary, as required by Maxwell's equations, is imposed, thus coupling the two methods to obtain a consistent solution. The coupling term is expressed by a surface integral formed by the dot product of a FE basis function and an IE testing function, or

viceversa. By choosing the boundary to be a surface of revolution and by making a convenient selection of IE basis (testing) functions, it is possible to evaluate the integrals analytically on surfaces such as curved triangles, curved quadrilaterals and curved pentagons. We will illustrate the salient steps involved in setting up and carrying out these integrals and discuss what class of basis (testing) functions and analytic surfaces of revolution they are applicable to. Analytic calculations offer the advantage of better accuracy than purely numerical ones, and, when combined with them, often shed light on issues of numerical convergence and limiting values. Furthermore, they may reduce computation time and storage requirements. Author

Natural and man-made events like earthquakes and nuclear explosions launch atmospheric gravity waves (AGW) into the atmosphere. Since the particle density decreases exponentially with height, the gravity waves increase exponentially in amplitude as they propagate toward the upper atmosphere and ionosphere. As atmospheric gravity waves approach the ionospheric heights, the neutral particles carried by gravity waves collide with electrons and ions, setting these particles in motion. This motion of charged particles manifests itself by wave-like fluctuations and disturbances that are known as traveling ionospheric disturbances (TID). The perturbation in the total electron content due to TID's is derived analytically from first principles. Using the tilted dipole magnetic field approximation and a Chapman layer distribution for the electron density, the variations of the total electron content versus the line-of-sight direction are numerically analyzed. The temporal variation associated with the total electron content measurements due to AGW's can be used as a means of detecting characteristics of the gravity waves. As an example, detection of tsunami generated earthquakes from their associated atmospheric gravity waves using the Global Positioning System is simulated. Author

POLARIMETRIC BACKSCATTERING FROM SEA ICE Abstract Only **c48**
S. V. Nghiem, R. Kwok, and S. H. Yueh *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 477 (For primary document see N94-20403 05-32)

Polarimetric backscattering from sea ice is presented. Theoretical models for backscattering are first presented for various ice types. Then, theoretical results are compared with experimental data for new thin ice, first-year ice, and multi-year ice. Sea ice is modeled as a layer medium containing random scatterers and rough interfaces. For multi-year sea ice with snow cover, the sea ice layer is modeled as an ice background with embedded spheroidal air bubbles and the snow layer as air with ice grains. The hummocky topography on multi-year ice is characterized by a Gaussian distribution which has an averaging effect on backscattering coefficients. First-year sea ice is described by an ice medium hosting ellipsoidal brine inclusions. These inclusions are oriented preferentially in the vertical direction due to the columnar structure of first-year sea ice. Azimuthally, the orientation of the brine pockets are random corresponding to the random c-axes in sea ice, unless the axes are oriented by sea currents. For thin ice in newly opened leads, it has been observed that there exists a thin brine layer with very high salinity on the top surface of the new ice. This brine layer is depicted as a medium with high permittivity which can significantly affect electromagnetic scattering signatures from the lower thin ice layer, with a higher fractional volume of brine inclusions due to higher salinity as compared to thick first-year sea ice. The rough medium interfaces are described as Gaussian rough surfaces characterized by root-mean-square heights and surface correlation lengths. The contribution from rough surface, calculated under the Kirchhoff approximation or small perturbation method, is assumed to be independent from volume scattering. The total loss including absorption and scattering losses in the scattering media is represented by the imaginary part of effective permittivity obtained from the strong fluctuation theory. The polarimetric scattering coefficients for different ice types are then derived under the distorted Born approximation. Author

Ridges and keels (hummocks and bummocks) in sea ice flows are important in sea ice research for both scientific and practical reasons. Sea ice movement and deformation is driven by internal and external stresses on the ice. Ridges and keels play important roles in both cases because they determine the external wind and current stresses via drag coefficients. For example, the drag coefficient over sea ice can vary by a factor of several depending on the fluid mechanical roughness length of the surface. This roughness length is thought to be strongly dependent on the ridge structures present. Thus, variations in ridge and keel structure can cause gradients in external stresses which must be balanced by internal stresses and possibly fracture of the ice. Ridging in sea ice is also a sign of fracture. In a practical sense, large ridges form the biggest impediment to surface travel over the ice or penetration through sea ice by ice-strengthened ships. Ridges also play an important role in the damage caused by sea ice to off-shore structures. Hence, observation and measurement of sea ice ridges is an important component of sea ice remote sensing. The research reported here builds on previous work, estimating the characteristics of ridges and leads in sea ice from SAR images. Our objective is to develop methods for quantitative measurement of sea ice ridges from SAR images. To make further progress, in particular, to estimate ridge height, a scattering model for ridges is needed. Our research approach for a ridge scattering model begins with a survey of the geometrical properties of ridges and a comparison with the characteristics of the surrounding ice. For this purpose we have used airborne optical laser (AOL) data collected during the 1987 Greenland Sea Experiment. These data were used to generate a spatial wavenumber spectrum for height variance for a typical ridge - the typical ridge is the average over 10 large ridges. Our first-order model radar scattering includes both the quasi-specular and Bragg resonant scatter mechanisms. This model is extended to include contributions from volume scatter and scatter from discrete objects. Geometrical characteristics from the AOL survey and model calculations imply that for radar wavelengths and observation geometries that are dominated by the quasi-specular scattering mechanism radar backscatter from a ridge is a measure of peak ridge height. We present scattering model results and compare them with ridges observed during the LEADEX experiment of March-April 1992 when both X, C, and L-band aircraft SAR and the ERS-1 satellite SAR observed a region in the Beaufort Sea near 86 deg N, 10 deg W. Data were also collected documenting ridge characteristics on the surface. The surface

data are used to generate a SAR signature via the scattering model described above. The predicted SAR signatures compare well with the SAR observations. Author

We investigate how multifrequency and polarimetric synthetic aperture radar (SAR) imagery enhances present capability to discriminate different ice conditions in single-frequency, single-polarization satellite SAR data. Frequencies considered are C- (lambda = 5.6cm), L- (lambda = 24cm) and P- (lambda = 68cm) band. Radar backscatter characteristics of six radiometrically and polarimetrically distinct ice types are selected from a cluster analysis of the multifrequency polarimetric SAR data and used to classify SAR images. Validation of these ice conditions is based on information provided by aerial photos, weather and ice surface measurements acquired at an ice camp, together with airborne passive microwave imagery, and visual analysis of the SAR data. The six identified sea-ice types are: (1) multiyear sea-ice; (2) compressed first year ice; (3) first year rubble and ridges; (4) first year rough ice; (5) first year smooth ice; and (6) thin ice. Open water is absent in all analyzed data. Classification of the SAR imagery into those six ice types is performed using a Bayesian Maximum A Posteriori classifier. Two complete scenes acquired at different dates in different locations are classified. The scenes were chosen such that they are representative of typical ice conditions in the Beaufort Sea in March 1988 and because ancillary information is available for validating the segmentation of various ice surface conditions. We apply Cloude's decomposition to imaging radar polarimetry. We derive the general expressions for the eigenvalues and eigenvectors for the case of terrain with reflection symmetry, and show in detail how the decomposition results can guide the interpretation of scattering from vegetated areas. For multi-frequency polarimetric radar measurements of a clear-cut area, the decomposition leads us to conclude that the vegetation is probably thin compared to even the C-band radar wavelength of 6 cm. For a forested area, we notice an increased amount of even number of reflection scattering at P-band and L-band, probably the result of penetration through the coniferous canopy resulting in trunk-ground double reflection scattering. The scattering for the forested area is still dominated by scattering from randomly oriented cylinders, however. It is found that these cylinders are thicker than in the case of clear-cut areas, leading us to conclude that scattering from the branches probably dominate in this case. Author

DIRECTION ANGLE SENSITIVITY OF AGRICULTURAL FIELD BACKSCATTER WITH AIRSAR DATA Abstract Only **c43**
Pascale C. Dubois, Eric Rignot, and Jakob J. vanZyl *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 488 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

This paper presents a study of the direction angle sensitivity of radar backscatter from agricultural fields. The direction angle is defined as the angle between the incident plane and the perpendicular to the field row direction. Previous studies have concentrated on comparing the backscatter of agricultural fields imaged with 0, 45, and 90 degree direction angles. In contrast, this study concentrates on the backscatter changes occurring when the direction angle is modified by a few degrees or even by fractions of a degree. This is possible by using the output of the NASA/JPL AIRSAR processor, in which sixteen independent frames are formed, each one corresponding to the same radar scene imaged with a slightly different squint angle. The studied data set is an agricultural area in La Mancha, Spain acquired in June and July 1991 during the EFEDA experiment. This paper describes the observed backscatter variations of the agricultural fields with direction angle measured at P, L, and C bands. As expected, the backscatter is maximum for a 0 degree direction angle. For several fields, the backscatter at P and L bands drops by more than 10 dB for a 5 degree change in direction angle. Furthermore, the sensitivity to the direction angle decreases with increasing vegetation. The variations in backscatter are compared with model predictions. One model, which agrees with scatterometer data, underestimates the observed backscatter variations with direction angle by more than 10 dB. It does not take into account the possible coherent component of the radar signal. We believe the strong direction sensitivity of agricultural field backscatter obtained with SAR data is due to a Bragg resonant effect, resulting in a strong coherent return when the direction angle is zero. The observations are then projected to the case of spaceborne SAR data. Author

TIME-DOMAIN ANALYSIS OF PLANAR MICROSTRIP DEVICES USING A GENERALIZED YEE-ALGORITHM BASED ON UNSTRUCTURED GRIDS Abstract Only
Stephen D. Gedney (Kentucky Univ., Lexington.) and Faiza Lansing *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 561 (For primary document see N94-20403 05-32)

The generalized Yee-algorithm is presented for the temporal full-wave analysis of planar microstrip devices. This algorithm has the significant advantage over the traditional Yee-algorithm in that it is based on unstructured and irregular grids. The robustness of the generalized Yee-algorithm is that structures that contain curved conductors or complex three-dimensional geometries can be more accurately, and much more conveniently modeled using standard automatic grid generation techniques. This generalized Yee-algorithm is based on the the time-marching solution of the discrete form of Maxwell's equations in their integral form. To this end, the electric and magnetic fields are discretized over a dual, irregular, and unstructured grid. The primary grid is assumed to be composed of general fitted polyhedra distributed throughout the volume. The secondary grid (or dual grid) is built up of the closed polyhedra whose edges connect the centroid's of adjacent primary cells, penetrating shared faces. Faraday's law and Ampere's law are used to update the fields normal to the primary and secondary grid faces, respectively. Subsequently, a correction scheme is introduced to project the normal fields onto the grid edges. It is shown that this scheme is stable, maintains second-order accuracy, and preserves the divergenceless nature of the flux densities. Finally, for computational efficiency the algorithm is structured as a series of sparse matrix-vector multiplications. Based on this scheme, the generalized Yee-algorithm has been implemented on vector and parallel high performance computers in a highly efficient manner. Author

We describe a potential procedure for retrieving ice thickness from multi-frequency polarimetric SAR data for thin ice. This procedure includes first masking out the thicker ice types with a simple classifier and then deriving the thickness of the remaining pixels using a model-inversion technique. The technique used to derive ice thickness from polarimetric observations is provided by a numerical estimator or neural network. A three-layer perceptron implemented with the backpropagation algorithm is used in this investigation with several improved aspects for a faster convergence rate and a better accuracy of the neural network. These improvements include weight initialization, normalization of the output range, the selection of offset constant, and a heuristic learning algorithm. The performance of the neural network is demonstrated by using training data generated by a theoretical scattering model for sea ice matched to the database of interest. The training data are comprised of the polarimetric backscattering coefficients of thin ice and the corresponding input ice parameters to the scattering model. The retrieved ice thickness from the theoretical backscattering coefficients is compare with the input ice thickness

to the scattering model to illustrate the accuracy of the inversion method. Results indicate that the network convergence rate and accuracy are higher when multi-frequency training sets are presented. In addition, the dominant backscattering coefficients in retrieving ice thickness are found by comparing the behavior of the network trained backscattering data at various incidence angels. After the neural network is trained with the theoretical backscattering data at various incidence anges, the interconnection weights between nodes are saved and applied to the experimental data to be investigated. In this paper, we illustrate the effectiveness of this technique using polarimetric SAR data collected by the JPL DC-8 radar over a sea ice scene. Author

We have used Ku-band (14.6 GHz) Seasat scatterometer (SASS) measurements to study changes in the backscatter of the Greenland ice sheet in response to seasonal changes in the surface and subsurface characteristics of the snow and glacial ice. To overcome the limitations imposed by the 50 km resolution of the SASS measurement, a resolution enhancement algorithm was used to generate 10 km resolution images of the backscatter response. To generate the images, the observed sigma(sup 0) (in dB) was modeled as a linear function of incidence angle theta, i.e., sigma(sup 0)(theta) = A + B(theta - 40 degrees) where theta epsilon (23 degrees, 55 degrees). The variable A can be thought of as the 'incidence angle-normalized sigma(sup 0)', while the gradient B describes the incidence angle dependence of sigma(sup 0). A time-series (one image every two weeks) of vertical and horizontally-polarized A and B was generated spanning a 100 day period between Julian Dates 180 and 280 (i.e. 29 June and 7 October) in 1978. This time series dramatically shows the effects of the summer melt and a clear transition with fall cooling and snowfall towards a typical winter scattering situation. The images also clearly delineate a number of principal snow and ice 'facies' which are identifiable on the surface. Author

RADAR BACKSCATTERING FROM SNOW FACIES OF THE GREENLAND ICE SHEET: RESULTS FROM THE AIRSAR 1991 CAMPAIGN Abstract Only **c48**
Eric Rignot, K. Jezek (Ohio State Univ., Columbus.), J. J. vanZyl, Mark R. Drinkwater, and Y. L. Lou *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 576 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

In June 1991, the NASA/JPL airborne SAR (AIRSAR) acquired C- (lambda = 5.6cm), L- (lambda = 24cm), and P- (lambda = 68m) band polarimetric SAR data over the Greenland ice sheet. These data are processed using version 3.55 of the AIRSAR processor which provides radiometrically and polarimetrically calibrated images. The internal calibration of the AIRSAR data is cross-checked using the radar response from corner reflectors deployed prior to flight in one of the scenes. In addition, a quantitative assessment of the noise power level at various frequencies and polarizations is made in all the scenes. Synoptic SAR data corresponding to a swath width of about 12 by 50 km in length (compared to the standard 12 x 12 km size of high-resolution scenes) are also processed and calibrated to study transitions in radar backscatter as a function of snow facies at selected frequencies and polarizations. The snow facies on the Greenland ice sheet are traditionally categorized based on differences in melting regime during the summer months. The interior of Greenland corresponds to the dry snow zone where terrain elevation is the highest and no snow melt occurs. The lowest elevation boundary of the dry snow zone is known traditionally as the dry snow line. Beneath it is the percolation zone where melting occurs in the summer and water percolates through the snow freezing at depth to form massive ice lenses and ice pipes. At the downslope margin of this zone is the wet snow line. Below it, the wet snow zone corresponds to the lowest elevations where snow remains at the end of the summer. Ablation produces enough meltwater to create areas of snow saturated with water, together with ponds and lakes. The lowest altitude zone of ablation sees enough summer melt to remove all traces of seasonal snow accumulation, such that the surface comprises bare glacier ice. Author

C-BAND RADAR BACKSCATTER OF SEA ICE IN THE WEDDELL SEA, ANTARCTICA DURING THE AUSTRAL WINTER OF 1992 Abstract Only
R. Hosseinmostafa (Kansas Univ. Center for Research, Inc., Lawrence.), Mark R. Drinkwater, S. P. Gogineni (Kansas Univ. Center for Research, Inc., Lawrence.), and W. Dierking (Alfred-Wegener-Inst. for Polar Research, Bremerhaven, Germany.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 578 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

A C-band ship-based scatterometer was used to measure the backscatter coefficient of sea ice in the Weddell Sea during June and July 1992. These are the first microwave scatterometer data ever to be collected in the Antarctic sea ice cover during the austral winter. The instrument was a frequency-modulated continuous-wave (FM-CW) radar altimeter modified by the University of Kansas Radar Systems and Remote Sensing Laboratory to perform backscatter measurements. Measurements were taken as part of a Jet Propulsion Laboratory experiment aboard the German ice research vessel F.S. Polarstern. Backscatter measurements were performed at incidence angles ranging from 17 to 65 degrees with VV and HV polarization as the Polarstern travelled from east to west across the central Weddell Sea. Backscatter measurements were made of several different types of ice sea including pancake, dark nilas, white nilas, grey, first-year and second-year ice. Periodic external calibrations were performed with the aid of a Luneberg Lens to enable absolute values of backscatter to be derived from the data. At each radar measurement location, in-situ measurements were made of snow and sea ice. Physical and chemical analyses of ice core and snow samples, together with high magnification photography of snow crystallography provide important information with which to develop physical models of the scattering systems. Meteorological information and oceanographic conditions were also recorded throughout the experiment. Many of the stations were chosen to coincide with periods of near-simultaneous or coincident imaging by the ERS-1 satellite Synthetic Aperture Radar (SAR). This enabled spaceborne imaging by the C-band SAR of areas of sea ice in which backscatter measurements were taken. This provides a valuable tool for interpretation of satellite SAR imagery from Antarctic sea ice in terms of the physical properties of the sea ice and snow. Preliminary results of the backscatter from the various ice types and their relation to the physical properties of sea ice are presented.

AN EFFICIENT FORMULATION OF THE COUPLED FINITE ELEMENT-INTEGRAL EQUATION TECHNIQUE FOR SOLVING LARGE 3D SCATTERING PROBLEMS Abstract Only **c64**
T. Cwik, V. Jamnejad, and C. Zuffada *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 604 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

It is often desirable to calculate the electromagnetic fields inside and about a complicated system of scattering bodies, as well as in their far-field region. The finite element method (FE) is well suited to solving the interior problem, but the domain has to be limited to a manageable size. At the truncation of the FE mesh one can either impose approximate (absorbing) boundary conditions or set up an integral equation (IE) for the fields scattered from the bodies. The latter approach is preferable since it results in higher accuracy. Hence, the two techniques can be successfully combined by introducing a surface that encloses the scatterers, applying a FE model to the inner volume and setting up an IE for the tangential fields components on the surface. Here the continuity of the tangential fields is used bo obtain a consistent solution. A few coupled FE-IE methods have recently appeared in the literature. The approach presented here has the advantage of using edge-based finite elements, a type of finite elements with degrees of freedom associated with edges of the mesh. Because of their properties, they are better suited than the conventional node based elements to represent electromagnetic fields, particularly when inhomogeneous regions are modeled, since the node based elements impose an unnatural continuity of all field components across boundaries of mesh elements. Additionally,

our approach is well suited to handle large size problems and lends itself to code parallelization. We will discuss the salient features that make our approach very efficient from the standpoint of numerical computation, and the fields and RCS of a few objects are illustrated as examples. Author

One of the promising combinations of finite element approaches for scattering problems uses Whitney edge elements, spherical vector wave-absorbing boundary conditions, and bi-conjugate gradient solution for the frequency-domain near field. Each of these approaches may be criticized. Low-order elements require high mesh density, but also result in fast, reliable iterative convergence. Spherical wave-absorbing boundary conditions require additional space to be meshed beyond the most minimal near-space region, but result in fully sparse, symmetric matrices which keep storage and solution times low. Iterative solution is somewhat unpredictable and unfriendly to multiple right-hand sides, yet we find it to be uniformly fast on large problems to date, given the other two approaches. Implementation of these approaches on a distributed memory, message passing machine yields huge dividends, as full scalability to the largest machines appears assured and iterative solution times are well-behaved for large problems. We present times and solutions for computed RCS for a conducting cube and composite permeability/conducting sphere on the Intel ipsc860 with up to 16 processors solving over 200,000 unknowns. We estimate problems of approximately 10 million unknowns, encompassing 1000 cubic wavelengths, may be attempted on a currently available 512 processor machine, but would be exceedingly tedious to prepare. The most severe bottlenecks are due to the slow rate of mesh generation on non-parallel machines and the large transfer time from such a machine to the parallel processor. One solution, in progress, is to create and then distribute a coarse mesh among the processors, followed by systematic refinement within each processor. Elimination of redundant node definitions at the mesh-partition surfaces, snap-to-surface post processing of the resulting mesh for good modelling of curved surfaces, and load-balancing redistribution of new elements after the refinement are auxiliary steps expected to result in a robust low i/o system for very large finite element problems. We investigate the behavior of the scattered electromagnetic waves from non-Gaussian ocean surfaces at near grazing incidence. Even though the scattering mechanisms at moderate incidence angles are relatively well understood, the same is not true for near grazing rough surface scattering. However, from the experimental ocean scattering data, it has been observed that the backscattering cross section of a horizontally polarized wave can be as large as the vertical counterpart at near grazing incidence. In addition, these returns are highly intermittent in time. There have been some suggestions that these unexpected effects may come from shadowing or feature scattering. Using numerical scattering simulations, it can be shown that the horizontal backscattering cannot be larger than the vertical one for the Gaussian surfaces. Our main objective of this study is to gain a clear understanding of scattering mechanisms underlying the near grazing ocean scattering. In order to evaluate the backscattering cross section from ocean surfaces at near grazing incidence, both the hydrodynamic modeling of ocean surfaces and an accurate near grazing scattering theory are required. For the surface modeling, we generate Gaussian surfaces from the ocean surface power spectrum which is derived using several experimental data. Then, weakly nonlinear large scale ocean surfaces are generated following Longuet-Higgins. In addition, the modulation of small waves by large waves is included using the conservation of wave action. For surface scattering, we use MOM (Method of Moments) to calculate the backscattering from scattering patches with the two scale shadowing approximation. The differences between Gaussian and non-Gaussian surface scattering at near grazing incidence are presented. Author

Ever since Crombie used the Doppler spectrum of RF signals scattered from the ocean surface to provide conclusive evidence for Bragg resonant scattering, scattering from the ocean surface has served as a testing ground for the identification of governing scattering mechanisms in rough surface scattering. The moving ocean surface has the advantage for rough surface scattering that, being a dispersive medium, features with different spatial scales the tendency to travel at different speeds. Thus, by looking at the temporal signature of the scattered field, one can try to isolate the scattering mechanism. This feature has been exploited by various authors. To give a recent example, we cite the work of Plant, who examined the Doppler spectrum of the return signal to infer the presence of two-scale scattering in scattering at medium incidence angles. The problem with restricting oneself to the examination of the Doppler spectrum, as has been done traditionally, is that one restricts the phenomena under investigation to temporally homogeneous phenomena: transient phenomena, which are localized in time, are not localized in frequency space. There is increasing evidence that this type of phenomena, due to specular scattering or breaking waves, may also play an important role in determining the scattering mechanism in ocean-like surfaces. To overcome this problem, we introduce the use of the Wavelet Transform to study the frequency-temporal signatures of the scattered field from moving ocean waves. We calculate this signature using various analytic scattering theories and show that the Wavelet Transform provides a useful tool for separating the different scattering mechanisms operating in scattering in ocean-like surfaces. Next we simulate realistic nonlinear moving ocean waves and calculate the temporal scattered field signature by using the method of moments and the stop-start approximation: the surface is assumed stationary during a scattering event, but moves between incident EM pulses. We compute and compare the Doppler frequency spectrum and the Wavelet Transform of the resulting signal for various types of surfaces and show how different scattering mechanisms may be isolated by this technique. Finally, we compare these numerical results against the analytical predictions in order to obtain the domain of applicability of various scattering theories for moving ocean surfaces which may include wave breaking and specular glints. THE EFFECT OF DISSIPATIVE INHOMOGENEOUS MEDIUM ON THE STATISTICS OF THE WAVE INTENSITY Abstract Only
Sasan S. Saatchi *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 620 (For primary document see N94-20403 05-32)

One of the main theoretical points in the theory of wave propagation in random medium is the derivation of closed form equations to describe the statistics of the propagating waves. In particular, in one dimensional problems, the closed form representation of the multiple scattering effects is important since it contributes in understanding such problems like wave localization, backscattering enhancement, and intensity fluctuations. In this the propagation of plane waves in a layer of one-dimensional dissipative random medium is considered. The medium is modeled by a complex permittivity whose real part is a constant representing the absorption. The one dimensional problem is mathematically equivalent to the analysis of a transmission line with randomly perturbed distributed parameters and a single mode lossy waveguide and the results can be used to study the propagation of radio waves through atmosphere and the remote sensing of geophysical media. It is assumed the scattering medium consists of an ensemble of one-dimensional point scatterers randomly positioned in a layer of thickness L with diffuse boundaries. A Poisson impulse process with density lambda is used to model the position of scatterers in the medium. By employing the Markov properties of this process an exact closed form equation of Kolmogorov-Feller type was obtained for the

probability density of the reflection coefficient. This equation was solved by combining two limiting cases: (1) when the density of scatterers is small; and (2) when the medium is weakly dissipative. A two variable perturbation method for small lambda was used to obtain solutions valid for thick layers. These solutions are then asymptotically evaluated for small dissipation. To show the effect of dissipation, the mean and fluctuations of the reflected power are obtained. The results were compared with a lossy homogeneous medium and with a lossless inhomogeneous medium and the regions where the effect of absorption is not essential were discussed. Author (revised)

Recent theoretical works have suggested the potential of passive polarimetry in the remote sensing of geophysical media. It was shown that the third Stokes parameter U of the thermal emission may become larger for azimuthally asymmetric fields of observation. In order to investigate the potential applicability of passive polarimetry to the remote sensing of ocean surface, measurements of the polarimetric thermal emission from a sinusoidal water surface and a numerical study of the polarimetric thermal emission from randomly rough ocean surfaces were performed. Measurements of sinusoidal water surface thermal emission were performed using a sinusoidal water surface which was created by placing a thin sheet of fiberglass with a sinusoidal profile in two dimensions extended infinitely in the third dimension onto a water surface. The theory of thermal emission from a 'two-layer' periodic surface is derived and the exact solution is performed using both the extended boundary condition method (EBC) and the method of moments (MOM). The theoretical predictions are found to be in good agreement with the experimental results once the effects of the radiometer antenna pattern are included and the contribution of background noise to the measurements is modeled. The experimental results show that the U parameter indicates the direction of periodicity of the water surface and can approach values of up to 30 K for the surface observed. Next, a numerical study of polarimetric thermal emission from randomly rough surfaces was performed. A Monte Carlo technique utilizing an exact method for calculating thermal emission was chosen for the study to avoid any of the limitations of the commonly used approximate methods in rough surface scattering. In this Monte Carlo technique, a set of finite rough surface profiles in two dimensions with desired statistics was generated and extended periodically. The polarimetric thermal emission from each surface of the set was then calculated using both the EBC and the MOM and the results were averaged. The surface statistics chosen were intended to model a wind perturbed ocean surface in the X to Ku band microwave region. The results indicate that the U parameter is sensitive to the azimuthal angle between the surface periodicity and the looking angle and to the rms height of the surface, and that the U parameter is fairly insensitive to variations in polar angle, permittivity, surface power law spectrum, and surface spectrum high frequency cutoff. These properties give further strength to the idea of using the U parameter to detect wind direction over the ocean. Author (revised)

OPTICAL BEAM FORMING TECHNIQUES FOR PHASED ARRAY ANTENNAS Abstract Only

Te-Kao Wu and C. Chandler *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 694 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Conventional phased array antennas using waveguide or coax for signal distribution are impractical for large scale implementation on satellites or spacecraft because they exhibit prohibitively large system size, heavy weight, high attenuation loss, limited bandwidth, sensitivity to electromagnetic interference (EMI) temperature drifts and phase instability. However, optical beam forming systems are smaller, lighter, and more flexible. Three optical beam forming techniques are identified as applicable to large spaceborne phased array antennas. They are (1) the optical fiber replacement of conventional RF phased array distribution and control components, (2) spatial beam forming, and (3) optical beam splitting with integrated quasi-optical components. The optical fiber replacement and the spatial beam forming approaches were pursued by many organizations. Two new optical beam forming architectures are presented. Both architectures involve monolithic integration of the antenna radiating elements with quasi-optical grid detector arrays. The advantages of the grid detector array in the optical process are the higher power handling capability and the dynamic range. One architecture involves a modified version of the original spatial beam forming approach. The basic difference is the spatial light modulator (SLM) device for controlling the aperture field distribution. The original liquid crystal light valve SLM is replaced by an optical shuffling SLM, which was demonstrated for the 'smart pixel' technology. The advantages are the capability of generating the agile beams of a phased array antenna and to provide simultaneous transmit and receive functions. The second architecture considered is the optical beam splitting approach. This architecture involves an alternative amplitude control for each antenna element with an optical beam power divider comprised of mirrors and beam splitters. It also implements the quasi-optical grid phase shifter for phase control and grid amplifier for RF power. The advantages are no SLM is required for this approach, and the complete antenna system is capable of full monolithic integration. Author (revised)

SIMULATED RETRIEVAL OF LAND SURFACE PARAMETERS USING MULTICHANNEL SATELLITE MICROWAVE RADIOMETRY Abstract Only **c43**

Eni G. Njoku and Brian Rague *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 764 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

The current global change research emphasis on understanding water and energy fluxes at the land-atmosphere interface provided renewed interest in using passive microwave satellite data for land studies. Radiative transfer models of microwave emission and scattering in the soil-vegetation-atmosphere column, though still in the process of development, can be used to estimate the accuracies with which land surface parameters can be derived from satellite data. These parameters include surface soil moisture, surface temperature, vegetation water content, and atmospheric water content. A microwave radiative transfer model is used to develop linear and nonlinear versions of a multichannel retrieval algorithm to simulate retrievals of the surface and atmospheric parameters. These simulations include the effect of additive noise, and examine the effects of nonlinearities in the radiative transfer models. However, effects of spatial heterogeneity are not considered. Satellite data to which the retrieval algorithms may be applied include the SSMR and SSM/I, and in future will include the Multifrequency Imaging Microwave Radiometer (MIMR) to be launched as part of the Earth Observing System (EOS). The Scanning Multichannel Microwave Radiometer (SMMR) on the Nimbus-7 satellite provided data from 1978 to 1987 at five microwave frequencies between 6.6 and 37 GHz. The series of Special Sensor Microwave/Imager (SSM/I) instruments launched on the DMSP satellites provide data from 1987 to the present at four frequencies between 19.35 and 8.5 GHz. Spatial resolutions of the data range from approximately 12 to 120 km depending on the frequency. Examples using data from these sensors are shown to indicate the results of applying retrieval algorithms based on model simulations to real data. Author (revised)

SYNERGISM OF ACTIVE AND PASSIVE MICROWAVE DATA FOR ESTIMATING BARE SURFACE SOIL MOISTURE Abstract Only **c43**

Sasan S. Saatchi, Eni G. Njoku, and Urs Wegmueller (Bern Univ., Switzerland.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 769 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Active and passive microwave sensors were applied effectively to the problem of estimating the surface soil moisture in a variety of environmental conditions. Research to date has shown that both types of sensors are

also sensitive to the surface roughness and the vegetation cover. In estimating the soil moisture, the effect of the vegetation and roughness are often corrected either by acquiring multi-configuration (frequency and polarization) data or by adjusting the surface parameters in order to match the model predictions to the measured data. Due to the limitations on multi-configuration spaceborne data and the lack of a priori knowledge of the surface characteristics for parameter adjustments, it was suggested that the synergistic use of the sensors may improve the estimation of the soil moisture over the extreme range of naturally occurring soil and vegetation conditions. To investigate this problem, the backscattering and emission from a bare soil surface using the classical rough surface scattering theory were modeled. The model combines the small perturbation and the Kirchhoff approximations in conjunction with the Peak formulation to cover a wide range of surface roughness parameters with respect to frequency for both active and passive measurements. In this approach, the same analytical method was used to calculate the backscattering and emissivity. Therefore, the active and passive simulations can be combined at various polarizations and frequencies in order to estimate the soil moisture more actively. As a result, it is shown that (1) the emissivity is less dependent on the surface correlation length, (2) the ratio of the backscattering coefficient (HH) over the surface reflectivity (H) is almost independent of the soil moisture for a wide range of surface roughness, and (3) this ratio can be approximated as a linear function of the surface rms height. The results were compared with the data obtained by a multi-frequency radiometer-scatterometer system working at frequencies between 3.0 GHz to 11.0 GHz. The data were acquired over bare soil surfaces with moisture variations due to freezing and thawing and roughness changes due to rain and erosion. The model predictions are shown to be in reasonable agreement with the data. In addition, it was shown that the same ratio when calculated from the data shows almost no dependence on the soil moisture. Finally, a simple technique which combines the backscattering coefficient at HH polarization (active sensing) with the emissivity at H polarization (passive sensing) is suggested for retrieving the soil moisture from bare soil surfaces.

POLARIMETRIC THERMAL EMISSION FROM PERIODIC WATER SURFACES Abstract Only **c43**

S. H. Yueh, S. V. Nghiem, R. Kwok, W. J. Wilson, F. K. Li, J. T. Johnson (Massachusetts Inst. of Tech., Cambridge.), and J. A. Kong (Massachusetts Inst. of Tech., Cambridge.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 770 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Experimental results and theoretical calculations are presented to study the polarimetric emission from water surfaces with directional features. For our ground-based Ku-band radiometer measurements, a water pool was constructed on the roof of a building in the Jet Propulsion Laboratory, and a fiberglass surface with periodic corrugations in one direction was impressed on the top of the water surface to create a stationary water surface underneath it. It is observed that the measured Stokes parameters of corrugated fiberglass-covered water surfaces are functions of azimuth angles and agree very well with the theoretical calculations. The theory, after being verified by the experimental data, was then used to calculate the Stokes parameters of periodic surfaces without fiberglass surface layer and with rms height of the order of wind-generated water ripples. The magnitudes of the azimuthal variation of the calculated emissivities at horizontal and vertical polarizations corresponding to the first two Stokes parameters are found to be comparable to the values measured by airborne radiometers and SSM/I. In addition, the third Stokes parameter not shown in the literature is seen to have approximately twice the magnitude of the azimuth variation of either T(sub h) or T(sub v), which may make it more sensitive to the row direction, while less susceptive to noises because the atmospheric and system noises tend to be unpolarized and are expected to be cancelled out when the third Stokes parameter is derived as the difference of two or three power measurements, as indicated by another experiment carried out at a swimming pool with complicated surroundings. The results indicate that passive polarimetry is a potential technology in the remote sensing of ocean wind vector which is a crucial component in the understanding of global climate change. Issues related to the application of microwave passive polarimetry to ocean wind are also discussed.

MULTIPLE SCATTERING EFFECTS ON THE LINEAR DEPOLARIZATION RATIO (LDR) MEASURED DURING CaPE BY A Ka-BAND AIR-BORNE RADAR Abstract Only

Toshio Iguchi (Universities Space Research Association, Greenbelt, MD.) and Robert Meneghini *In* JPL, Progress In Electromagnetics Research Symposium (PIERS) 1993 p 774 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Air-borne radar measurements of thunderstorms were made as part of the CaPE (Convection and Precipitation/Electrification) experiment in Florida in July 1991. The radar has two channels, X-band (10 GHz) and Ka-band (34.5 GHz), and is capable of measuring cross-polarized returns as well as co-polarized returns. In stratiform rain, the cross-polarized components can be observed only at the bright band region and from the surface reflection. The linear depolarization ratios (LDR's) measured at X-band and Ka-band at the bright band are nearly equal. In convective rain, however, the LDR in Ka-band often exceeds the X-band LDR by several dB, and sometimes by more than 10 dB, reaching LDR values of up to -5 dB over heavy convective rain. For randomly oriented hydrometeors, such high LDR values cannot be explained by single scattering from non-spherical scattering particles alone. Because the LDR by single backscatter depends weakly on the wavelength, the difference between the Ka-band and X-band LDR's suggests that multiple scattering effects prevail in the Ka-band LDR. In order to test this inference, the magnitude of the cross-polarized component created by double scattering was calculated using the parameters of the airborne radar, which for both frequencies has beamwidths of 5.1 degrees and pulse widths of 0.5 microsecond. Uniform rain beyond the range of 3 km is assumed.

MULTI-BAND REFLECTOR ANTENNA WITH DOUBLE-RING ELEMENT FREQUENCY SELECTIVE SUBREFLECTOR Abstract Only

Te-Kao Wu and S. W. Lee (Illinois Univ., Urbana.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 788 (For primary document see N94-20403 05-32)

Avail: CASI HC A01/MF A10

Frequency selective subreflectors (FSS) are often employed in the reflector antenna system of a communication satellite or a deep space exploration vehicle for multi-frequency operations. In the past, FSS's have been designed for diplexing two frequency bands. For example, the Voyager FSS was designed to diplex S and X bands and the TDRSS FSS was designed to diplex S and Ku bands. Recently, NASA's CASSINI project requires an FSS to multiplex four frequency (S/X/Ku/Ka) bands. Theoretical analysis and experimental verifications are presented for a multi-band flat pannel FSS with double-ring elements. Both the exact formulation and the thin-ring approximation are described for analyzing and designing this multi-ring patch element FSS. It is found that the thin-ring approximation fails to predict the electrically wide ring element FSS's performance. A single screen double-ring element FSS is demonstrated for the tri-band system that reflects the X-band signal while transmitting through the S- and Ku-band signals. In addition, a double screen FSS with non-similar double-ring elements is presented for the Cassini's four-band system which reflects the X- and Ka-band signals while passing the S- and Ku-band signals. To accurately predict the FSS effects on a dual reflector antenna's radiation pattern, the FSS subreflector's transmitted/reflected field variation as functions of the polarization and incident angles with respect to the local coordinates was taken into account. An FSS transmission/reflection coefficient table is computed for TE and TM polarizations at various incident angles based on the planar FSS model. Next, the hybrid Geometric Optics (GO) and Physical Optics (PO) technique is implemented with linearly interpolating the FSS table to efficiently determine the FSS effects in a dual reflector antenna.

SECOND ORDER DISTORTED BORN APPROXIMATION FOR BACKSCATTERING FROM A LAYER OF DISCRETE RANDOM MEDIUM Abstract Only

Roger H. Lang (George Washington Univ., Washington, DC.) and Sasan S. Saatchi *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 806 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

In recent years there has been increasing interest in scattering and depolarization characteristics of the vegetation canopies. Scattering models applied to the microwave remote sensing of vegetation canopies showed that multiple scattering effects can be important in simulating the backscattering coefficients correctly. In particular, in most applications, the cross-polarized backscattering coefficients are often underestimated by single scattering models. Recently, there have been concerted efforts to include the second order terms in the radiative transfer models of vegetation canopies in order to account for multiple scattering within the canopy. The coherent wave theory approach is extended to include multiple scattering effects to predict the coherent and incoherent backscattering contributions from a layer of vegetation canopy. The problem is initially formulated in terms of the exact equation for the correlation function of the field, i.e., the Bethe-Salpeter equation. Using fractional volume as a small parameter, a Foldy type approximation is made to obtain a more manageable correlation equation. This equation is iterated to obtain first and second order solutions. The iteration procedure assumes the variance of the field fluctuations are small compared to the coherent intensity. This assumption proved to be particularly successful in computing backscattering coefficients. First and second order backscattering coefficients are calculated from the iterants of the correlation equation. It is shown that the first order coefficients are the same as the distorted Born results used previously by the authors. These results contained enhancement terms in the direct-reflected contributions. The important contributions to second order backscattering are examined and interpreted in terms of scattering diagrams. Examples of situations in which second order backscattering coefficients are important are given.

Relationships among polarimetric backscattering coefficients are derived from the viewpoint of symmetry groups. For both reciprocal and non-reciprocal media, symmetry encountered in remote sensing due to reflection, rotation, azimuthal, and centrical symmetry groups is considered. The derived properties are general and valid to all scattering mechanisms, including volume and surface scatterings and their interactions, in a given symmetrical configuration. The scattering coefficients calculated from theoretical models for layer random media and rough surfaces are shown to obey the symmetry relations. Use of symmetry properties in remote sensing of structural and environmental responses of scattering media is also discussed. Orientations of spheroidal scatterers described by spherical, uniform, planophile, plagiothile, erectophile, and extremophile distributions are considered to derive their polarimetric backscattering characteristics. These distributions can be identified from the observed scattering coefficients by comparison with theoretical symmetry calculations. A new parameter is then defined to study scattering structures in geophysical media. Observations from polarimetric data acquired by the Jet Propulsion Laboratory airborne synthetic aperture radar over forests, sea ice, and sea surface are presented. Experimental evidences of the symmetry relationships are shown and their use in polarimetric remote sensing is illustrated. For forests, the coniferous forest in Mt. Shasta area (California) and mixed forest near Presque Isle (Maine) exhibit characteristics of the centrical symmetry at C-band. For sea ice in the Beaufort Sea, multi-year sea ice has a cross-polarized ratio e close to e(sub 0), calculated from symmetry, due to the randomness in the scattering structure. First-year sea ice has e much smaller than e(sub 0) due to the preferential alignment of the columnar structure of the ice. From polarimetric data of a sea surface in the Bering Sea, it is observed that e and e(sub 0) are increasing with incident angle and e is greater than e(sub 0) at L-band because of the directional feature of sea surface waves. Symmetry properties of geophysical media can also be used to calibrate polarimetric radars. Author (revised)

RELATIONSHIP OF ATTENUATION IN A VEGETATION CANOPY TO PHYSICAL PARAMETERS OF THE CANOPY Abstract Only **c43**

A discrete scatter model is employed to compute the radiometric response (i.e. emissivity) of a layer of vegetation over a homogeneous ground. This was done to gain insight into empirical formulas for the emissivity which have recently appeared in the literature and which indicate that the attenuation through the canopy is proportional to the water content of the vegetation and inversely proportional to wavelength raised to a power around unity. The analytical result assumes that the vegetation can be modeled by a sparse layer of discrete, randomly oriented particles (leaves, stalks, etc.). The attenuation is given by the effective wave number of the layer obtained from the solution for the mean wave using the effective field approximation. By using the Ulaby-El Rayes formula to relate the dielectric constant of the vegetation to its water content, it can be shown that the attenuation is proportional to water content. The analytical form offers insight into the dependence of the empirical parameters on other variables of the canopy, including plant geometry (i.e. shape and orientation of the leaves and stalks of which the vegetation is comprised), frequency of the measurement and even the physical temperature of the vegetation. Solutions are presented for some special cases including layers consisting of cylinders (stalks) and disks (leaves). Author

NUMERICAL MODELING FOR AN ELECTRIC-FIELD HYPERTHERMIA APPLICATOR Abstract Only **c52**
Te-Kao Wu, C. K. Chou (City of Hope Medical Center, Duarte, CA.), K. W. Chan (City of Hope Medical Center, Duarte, CA.), and J. McDougall (City of Hope Medical Center, Duarte, CA.) *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 824 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

Hyperthermia, in conjunction with radiation and chemotherapy for treatment of cancers, is an area of current concern. Experiments have shown that hyperthermia can increase the potency of many chemotherapy drugs and the effectiveness of radiation for treating cancer. A combination of whole body or regional hyperthermia with chemotherapy or radiation should improve treatment results. Conventional methods for inducing whole body hyperthermia, such as exposing a patient in a radiant cabinet or under a hot water blanket, conduct heat very slowly from the skin to the body core. Thus a more efficient system, such as the three-plate electric-field hyperthermia applicator (EHA), is developed. This three-plate EHA has one top plate over and two lower plates beneath the patient. It is driven at 27.12 MHz with 500 Watts through a matching circuit. Using this applicator, a 50 kg pig was successfully heated to 42 C within 45 minutes. However, phantom and animal studies have indicated non-uniform heating near the side of the body. In addition, changes in the size and distance between the electrode plates can affect the heating (or electromagnetic field) pattern. Therefore, numerical models using the method of moments (MOM) or the finite difference time domain (FDTD) technique are developed to optimize the heating pattern of this EHA before it is used for human trials. The accuracy of the numerical modeling has been achieved by the good agreement between the MOM and FDTD results for the three-plate EHA without a biological body. The versatile FDTD technique is then applied to optimize the EHA design with a human body. Both the numerical and measured data in phantom blocks will be presented. The results of this study will be used to design an optimized system for whole body or regional hyperthermia. Author (revised)

Avail: CASI HC A01/MF A10

A maximum a posteriori Bayesian classifier for multifrequency polarimetric SAR data is used to perform a supervised classification of forest types in the floodplains of Alaska. The image classes include white spruce, balsam poplar, black spruce, alder, non-forests, and open water. The authors investigate the effect on classification accuracy of changing environmental conditions, and of frequency and polarization of the signal. The highest classification accuracy (86 percent correctly classified forest pixels, and 91 percent overall) is obtained combining L- and C-band frequencies fully polarimetric on a date where the forest is just recovering from flooding. The forest map compares favorably with a vegetation map assembled from digitized aerial photos which took five years for completion, and address the state of the forest in 1978, ignoring subsequent fires, changes in the course of the river, clear-cutting of trees, and tree growth. HV-polarization is the most useful polarization at L- and C-band for classification. C-band VV (ERS-1 mode) and L-band HH (J-ERS-1 mode) alone or combined yield unsatisfactory classification accuracies. Additional data acquired in the winter season during thawed and frozen days yield classification accuracies respectively 20 percent and 30 percent lower due to a greater confusion between conifers and deciduous trees. Data acquired at the peak of flooding in May 1991 also yield classification accuracies 10 percent lower because of dominant trunk-ground interactions which mask out finer differences in radar backscatter between tree species. Combination of several of these dates does not improve classification accuracy. For comparison, panchromatic optical data acquired by SPOT in the summer season of 1991 are used to classify the same area. The classification accuracy (78 percent for the forest types and 90 percent if open water is included) is lower than that obtained with AIRSAR although conifers and deciduous trees are better separated due to the presence of leaves on the deciduous trees. Optical data do not separate black spruce and white spruce as well as SAR data, cannot separate alder from balsam poplar, and are of course limited by the frequent cloud cover in the polar regions. Yet, combining SPOT and AIRSAR offers better chances to identify vegetation types independent of ground truth information using a combination of NDVI indexes from SPOT, biomass numbers from AIRSAR, and a segmentation map from either one. APPLICATION OF THE TARGET DECOMPOSITION THEOREM TO A POLARIMETRIC RANDOM MEDIA MODEL Abstract Only
Sasan S. Saatchi and Jakob J. vanZyl *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 871 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

With advances in polarimetric radar measurements of land surfaces, the need for understanding the underlying scattering mechanisms and dominant target features has become the focus of many studies. In particular, the maximum use of the polarimetric information to identify and/or separate parameters related to the surface features such as vegetation thickness, structure, water content, and soil surface characteristics will enhance the possibility of using polarimetric radars for monitoring the earth's surface from space. In this paper, Cloude's decomposition theorem is applied to a polarimetric random media model to simulate the radar measurements of vegetated canopies. The vegetated canopies are modeled as a three layer discrete random medium with leaves and branches in the first layer, tree trunks in the second layer, and a half space of homogeneous ground with rough interface as the bottom layer. The distorted born approximation (DBA) has been used to compute full Mueller matrix of the canopy, using canonical dielectric objects such as thin discs and cylinders as leaves, branches, and trunks, respectively. The Mueller matrix and the derived covariance matrix contain information on the second order statistics of radar signals at various polarizations from the canopy. To decompose the covariance matrix to its constituent targets, the eigenvalues and eigenvectors of the covariance matrix are computed in terms of the physical parameters of the canopy. In addition, each eigenvector explicitly shows the scattering mechanisms such as odd and even reflections in the canopy. Cloude's decomposition theorem is applied using the Pauli spin matrices as a basis and an expression for the degree of disorder or the entropy for the vegetated surface is found. Then, the physical parameters estimated from in situ measurements are used in the random media to obtain realistic covariance matrices. As a result, the sensitivity of the eigenvalue spectrums and the coefficients resulting from the target decomposition theorem to the physical parameters of the canopy are examined and the possible use of Cloude's theorem to estimate vegetation and soil parameters is discussed. A THEORETICAL AND NUMERICAL STUDY OF POLARIMETRIC SCATTERING AND EMISSION FROM RANDOM ROUGH SURFACES WITH ANISOTROPIC DIRECTIONAL SPECTRUM Abstract Only
S. H. Yueh and R. Kwok *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 873 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

In this paper, theoretical and numerical results of the polarimetric scattering and emission from random rough surfaces with anisotropic directional spectrum are presented for the remote sensing of ocean and soil surfaces. The polarimetric scattered field for rough dielectric surfaces is derived to the second order by the small perturbation method (SPM). It is found that the second-order scattered field is coherent in nature, and its coefficients for different polarizations present the lowest-order corrections to the Fresnel reflection coefficients of the surfaces. In addition, the cross-polarized (HV and VH) components of the coherent fields are reciprocal and not zero for surfaces with anisotropic directional spectrum when the azimuth angle of the incident direction is not aligned with the symmetry directions of surfaces. In order to verify the energy conservation condition of the theoretical results, which is important if the theory is to be applied to the passive polarimetry of rough surfaces, a Monte Carlo simulation is performed to numerically calculate the polarimetric reflectivities of one-dimensional random rough surfaces which are generated with a prescribed power-law spectrum in the spectral domain and transformed to the spatial domain by the FFT. The surfaces simulated by this approach are periodic with the period corresponding to the low-wavenumber cutoff. To calculate the scattering from periodic dielectric surfaces, the authors present a new numerical technique which applies the Floquet theorem to reduce the problem to one period and does not require the evaluation of one-dimensional periodic Green's function used in the conventional method of moment formulation. Once the scattering coefficients are obtained, the polarimetric Stokes vectors for the emission from the random surfaces are then calculated according to the Kirchhoff's law and are illustrated as functions of relative azimuth observation and row directions. The second-order SPM is also reduced to this one-dimensional case, and theoretical results for all four Stokes parameters are in excellent agreement with the numerical results obtained from the Monte Carlo simulation. Moreover, the second order coherent fields are found to be necessary for the theoretical evaluation of the third and fourth Stokes parameters. Without that, the reflectivities of random rough surfaces are significantly over-estimated, and the signs of the third and the fourth Stokes parameters are found to be incorrect, if calculated by using the first-order incoherent fields alone. This paper investigates the potential application of neural network to inversion of soil moisture using polarimetric remote sensing data. The neural network used for the inversion of soil parameters is multi-layer perceptron trained with the back-propagation algorithm. The training data include the polarimetric backscattering coefficients obtained from theoretical surface scattering models together with an assumed nominal range of soil parameters which are comprised of the soil permittivity and surface roughness parameters. Soil permittivity is calculated from the soil moisture and the assumed soil texture based on an empirical formula at C-, L-, and P-bands. The rough surface parameters for the soil surface, which is described by the Gaussian random process, are the root-mean-square

(rms) height and correlation length. For the rough surface scattering, small perturbation method is used for the L-band frequency, and Kirchhoff approximation is used for the C-band frequency to obtain the corresponding backscattering coefficients. During the training, the backscattering coefficients are the inputs to the neural net and the output from the net are compared with the desired soil parameters to adjust the interconnecting weights. The process is repeated for each input-output data entry and then for the entire training data until convergence is reached. After training, the backscattering coefficients are applied to the trained neural net to retrieve the soil parameters which are compared with the desired soil parameters to verify the effectiveness of this technique. Several cases are examined. First, for simplicity, the correlation length and rms height of the soil surface are fixed while soil moisture is varied. Soil moisture obtained using the neural networks with either L-band or C-band backscattering coefficients for the HH and VV polarizations as inputs is in good agreement with the desired soil moisture. The neural net output matches the desired output for the soil moisture range of 16 to 60 percent for the C-band case. The next case investigated is to vary both soil moisture and rms height while keeping the correlation length fixed. For this case, C-band backscattering coefficients are not sufficient for retrieving two parameters because the Kirchhoff approximation gives the same HH and VV backscattering coefficients. Therefore, the backscattering coefficients at two different frequency bands are necessary to find both the soil moisture and rms height. Finally, the neural nets are also applied to simultaneously invert soil moisture, rms height, and correlation length. Overall, the soil moisture retrieved from the neural network agrees very well with the desired soil moisture. This suggests that the neural network shows potential for retrieval of soil parameters from remote sensing data. Author (revised)

For the double bounce case, where the radar signal is reflected twice before returning to the radar antenna, some polarization effects may be observed related to the dielectric constant of the two surfaces causing the reflections. The most noticeable effect would be that the returned signal would be preferentially H polarized. In fact, it may be possible to discern the Brewster angle for both surfaces. The locations of the Brewster angle will depend on the dielectric constant and permittivity of each surface. If it is assumed that both reflections are in the same plane of incidence, and that both surfaces are smooth and flat, there is a straightforward relationship between the degree of linear polarization m and both the dielectric constants of the two reflecting surfaces and the angle of incidence of the illuminating wave: m carat = cos 2(arccot (square root of (R(sub v) / R(sub h)))) where R(sub v,h) are the V and H polarized Fresnel reflection coefficients for two surfaces perpendicular to each other. The degree of linear polarization may be calculated from AIRSAR compressed Stokes data and compared with the given equation. The degree of linear polarization may also be calculated using tree models and compared with AIRSAR data. With further work, it may be possible to use the degree of linear polarization to determine surface parameters of certain imaged areas. Author (revised)

MOBILE ANTENNA DEVELOPMENT AT JPL Abstract Only
J. Huang, V. Jamnejad, A. Densmore, A. Tulintseff, R. Thomas, and K. Woo *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 880 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

The Jet Propulsion Laboratory (JPL), under the sponsorship of NASA, has pioneered the development of land vehicle antennas for commercial mobile satellite communications. Several novel antennas have been developed at L-band frequencies for the Mobile Satellite (MSAT) program initiated about a decade ago. Currently, two types of antennas are being developed at K- and Ka-band frequencies for the ACTS (Advanced Communications Technology Satellite) Mobile Terminal (AMT) project. For the future, several hand-held antenna concepts are proposed for the small terminals of the Ka-band Personal Access Satellite System (PASS). For the L-band MSAT program, a number of omni-directional low-gain antennas, such as the crossed drooping-dipoles, the higher-order-mode circular microstrip patch, the quadrifilar helix, and the wrapped-around microstrip 'mast' array, have been developed for lower data rate communications. Several medium-gain satellite tracking antennas, such as the electronically scanned low-profile phased array, the mechanically steered tilted microstrip array, the mechanically steered low-profile microstrip Yagi array, and the hybrid electronically/mechanically steered low-profile array, have been developed for the MSAT's higher data rate and voice communications. To date, for the L-band vehicle application, JPL has developed the world's lowest-profile phased array (1.8 cm height), as well as the lowest-profile mechanically steered antenna (3.7 cm height). For the 20/30 GHz AMT project, a small mechanically steered elliptical reflector antenna with a gain of 23 dBi has recently been developed to transmit horizontal polarization at 30 GHz and receive vertical polarization at 20 GHz. Its hemispherical radome has a height of 10 cm and a base diameter of 23 cm. In addition to the reflector, a mechanically steered printed MMIC active array is currently being developed to achieve the same electrical requirements with a low profile capability. These AMT antenna developments, along with other Ka-band technologies, will lead to the development of several compact hand-held terminals for the PASS program. A few antenna concepts, such as the lap-top or desk-top terminal's printed array, the hand-held phased array, and the head-mounted low-profile array, have been proposed to achieve a future vision for the personal access communications system. In this paper, the feasibility of using an L-band low gain antenna (LGA) as a mobile terminal antenna for helicopters is described. The objective is to select the lowest cost antenna system which can be easily mounted on a helicopter and capable of communicating with a geosynchronous satellite. To ensure that all the antenna options are being considered, the steerable high gain reflector and medium gain array antennas as well as LGA are studied and compared in an exhaustive survey. The high gain reflector antenna in L-band is usually very large in size and heavy in weight. In addition, a bulky and expensive tracking system is needed to steer the antenna beam to the satellite direction. The medium gain antennas (including mechanically and electronically steered arrays) are also more expensive and less reliable than an LGA due to the addition of a beam steering system to track the satellite. The omni-directional LGA is simple, reliable, and inexpensive. It is typically ten times smaller than the medium gain antenna. This makes the position, selection, and mounting on the helicopter relatively easier. Therefore, the LGA is selected as a mobile terminal antenna for helicopters. Among the many LGA's (cross-dipole, helix, spiral, and slot antennas), the helix antenna is the most inexpensive. One can also change the size, shape, or pitch angle of the helix to optimize the gain in the desired direction. Therefore, the helix antenna is selected for further study. Both 2-arm and 4-arm helices are studied theoretically and experimentally to determine the antenna's performance and the scattering effects from the helicopter body and the blades. The multipath, Doppler, and Doppler rate issues as well as the periodic fading effects caused by the helicopter rotor blades will be briefly discussed in the paper. Author (revised)

TOPOGRAPHIC SLOPE FROM THE SAR INTERFEROMETRIC PHASE GRADIENT Abstract Only **c43**
Charles L. Werner (Zurich Univ., Switzerland.) and Paul A. Rosen *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 922 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

A new algorithm for the direct calculation of topographic slope maps from synthetic aperture radar (SAR) interferograms is presented. The algorithm derives slope maps without first requiring the creation of a digital elevational model (DEM) from the interferogram, thus obviating the need for high SNR in the interferogram and altitude calibration points for the scene. SAR data useful for interferometry has been collected by the Active Microwave Imager on board the ERS-1 satellite, when it was in a short period repeat orbit. Two passes of the radar sensor form a cross-track

interferometric baseline. For a point target at some position (x,y,h), the interferometric phase difference phi is proportional to the difference in path lengths for the two sensor positions to the scatterer. Given the phase difference as measured in the complex interferogram and an accurate baseline geometry, the position of the scatterer, most significantly the height h, can be determined through triangulation. The interferometric phase measurement however is known only modulo 2-pi, and hence it is necessary to determine the correct multiple of 2-pi to add to the phase at each point to obtain an estimate of the actual phase with respect to an absolute datum. This phase unwrapping process is required for creating DEM's, and is difficult or impossible for regions of low SNR or SAR image layover. The new algorithm described here derives slope maps without requiring phase unwrapping. Author (revised)

INTERFEROMETRIC DETECTION OF FREEZE-THAW DISPLACEMENTS OF ALASKAN PERMAFROST USING ERS-1 DATA Abstract Only c43
Charles L. Werner (Zurich Univ., Switzerland.) and Andrew K. Gabriel *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 923 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

The possibility of making large scale (50 km) measurements of motions of the earth's surface with high resolution (10 m) and very high accuracy (1 cm) from multipass SAR interferometry was established in 1989. Other experiments have confirmed the viability and usefulness of the method. Work is underway in various groups to measure displacements from volcanic activity, seismic events, glacier motion, and in the present study, freeze-thaw cycles in Alaskan permafrost. The ground is known to move significantly in these cycles, and provided that freezing does not cause image decorrelation, it should be possible to measure both ground swelling and subsidence. The authors have obtained data from multiple passes of ERS-1 over the Toolik Lake region of northern Alaska of suitable quality for interferometry. The data are processed into images, and single interferograms are formed in the usual manner. Phase unwrapping is performed, and the multipass baselines are estimated from the images using both orbit ephemerides and scene tie points. The phases are scaled by the baseline ratio, and a double-difference interferogram (DDI) is formed. It is found that there is a residual 'saddle-shape' phase error across the image, which is postulated to be caused by a small divergence (10(exp -2) deg.) in the orbits. A simulation of a DDI from divergent orbits confirms the shape and magnitude of the error. A two-dimensional least squares fit to the error is performed, which is used to correct the DDI. The final, corrected DDI shows significant phase (altitude) changes over the period of the observation.

PERFORMANCE EVALUATION OF THE JPL TOPSAR SYSTEM: AN ACROSS-TRACK INTERFEROMETRIC SAR SYSTEM FOR TOPOGRAPHIC MAPPING Abstract Only c43
Soren N. Madsen, Howard A. Zebker, and Jan Martin *In its* Progress In Electromagnetics Research Symposium (PIERS) 1993 p 924 (For primary document see N94-20403 05-32)
Avail: CASI HC A01/MF A10

An across-track interferometric (XTI) SAR has the capability of determining the three dimensional target location from the recorded radar echos thus providing high spatial resolution both horizontally and vertically. The output of an XTI SAR will typically include both a radar backscatter map and a digital elevation model (DEM). The accuracy of the derived DEM is determined by factors such as data acquisition geometry, signal-to-noise ratio, knowledge of platform position and attitude as well as the accuracy of the processing system. In the summer of 1992 the authors acquired TOPSAR data over the Ft. Irwin area in California, a desert area with significant relief (height standard deviation 150 m). Very accurate DEM's have been derived for this area by the Topographic Engineering Center (TEC) using digital correlation methods on 1:20,000 scale digitized photographs. Corner reflectors were deployed in the area, and their locations were determined to cm accuracies by the Defense Mapping Agency (DMA) using differential GPS techniques. DEM's generated from the acquired radar data have been rotated and translated to overlay the reference DEM's provided by TEC. A detailed description of the errors and their characteristics will be given. The standard deviations of the radar data sets we acquired measured over a 5.6 by 7 km area were 1.9 and 2.3 m. The corresponding numbers for flat areas were 1.1 and 2.0 m and for mountain areas 3.3 and 2.2 m. Author (revised)

This document discusses the design, fabrication, and operation of an antenna array simulator, which is an integral part of the NRaD adaptive array evaluation facility. A brief introduction is provided to explain how adaptive receiving antenna arrays can improve Navy high-frequency communications and how this developmental work is supported at NRaD. The main body of the text encompasses both the software algorithms created to support computerized remote control and antenna phase-tuning operation and a detailed hardware description of the Simulator circuitry, which is suitable as a guide for maintenance and troubleshooting tasks.

(DE93-040390; LA-12622-T) Avail: CASI HC A07/MF A02

A wide range of research has been published on the problem of estimating the parameters of electromagnetic and acoustical sources from measurements of signals measured at an array of sensors. In the quasi-static electromagnetic cases examined here, the signal variation from a point source is relatively slow with respect to the signal propagation and the spacing of the array of sensors. As such, the location of the point sources can only be determined from the spatial diversity of the received signal across the array. The inverse source localization problem is complicated by unknown model order and strong local minima. The nonlinear optimization problem is posed for solving for the parameters of the quasi-static source model. The transient nature of the sources can be exploited to allow subspace approaches to separate out the signal portion of the spatial correlation matrix. Decomposition techniques are examined for improved processing, and an adaptation of MUltiple SIgnal Characterization (MUSIC) is presented for solving the source localization problem. Recent results on calculating the Cramer-Rao error lower bounds are extended to the multidimensional problem here. This thesis focuses on the problem of source localization in magnetoencephalography (MEG), with a secondary application to thunderstorm source localization. Comparisons are also made between MEG and its electrical equivalent, electroencephalography (EEG). The error lower bounds are examined in detail for several MEG and EEG configurations, as well as localizing thunderstorm cells over Cape Canaveral and Kennedy Space Center. Time-eigenspectrum is introduced as a parsing technique for improving the performance of the optimization problem.

A discrete peeled high electron mobility transistor (HEMT) device was integrated into a 10 GHz amplifier. The discrete HEMT device interconnects were made using photo patterned metal, stepping from the 10 mil alumina host substrate onto the 1.3 microns thick peeled GaAs HEMT layer, eliminating the need for bond wires and creating a fully integrated circuit. Testing of devices indicate that the peeled device is not degraded by the peel off step but rather there is an improvement in the quantum well carrier confinement. Circuit testing resulted in a maximum gain of 8.5 dB and a return loss minimum of -12 dB. Author (revised)

The performance characteristics of InP-based In(x)Ga(1-x)As/In(0.52)Al(0.48)As (0.53 is less than or equal to x is less than or equal to 0.70) pseudomorphic modulation-doped field-effect transistors (MODFET's) as a function of strain in the channel, gate, length, and temperature were investigated analytically and experimentally. The strain in the channel was varied by varying the In composition x. The temperature was varied in the range of 40-300 K and the devices have gate lengths L(sub g) of 0.8 and 0.2 microns. Analysis of the device was done using a one-dimensional self consistent solution of the Poisson and Schroedinger equations in the channel, a two-dimensional Poisson solver to obtain the channel electric field, and a Monte Carlo simulation to estimate the carrier transit times in the channel. An increase in the value of the cutoff frequency is predicted for an increase in In composition, a decrease in temperature, and a decrease in gate length. The improvements seen with decreasing temperature, decreasing gate length, and increased In composition were smaller than those predicted by analysis. The experimental results on pseudomorphic InGaAs/InAlAs MODFET's showed that there is a 15-30 percent improvement in cutoff frequency in both the 0.8- and 0.2-micron gate length devices when the temperature is lowered from 300 to 40 K.

A comprehensive theoretical and experimental study of straight and bent coplanar waveguide (CPW) shunt stubs is presented. In the theoretical analysis, the CPW is assumed to be inside a cavity, while, the experiments are performed on open structures. A hybrid technique was developed to analyze the CPW discontinuities which proved to be accurate since the theoretical and experimental results agree very well. The effect of the cavity resonances on the behavior of the stubs with and without air-bridges is investigated. In addition, the encountered radiation loss due to the discontinuities is evaluated experimentally. Author

(Grant NSF ECS-86-57951)
Avail: CASI HC A03/MF A03

A comparative study between open and shielded coplanar waveguide (CPW) discontinuities is presented. The space domain integral equation method is used to characterize several discontinuities such as the open-end CPW and CPW series stubs. Two different geometries of CPW series stubs (straight and bent stubs) are compared with respect to resonant frequency and radiation loss. In addition, the encountered radiation loss due to different CPW shunt stubs is evaluated experimentally. The notion of forced radiation simulation is presented, and the results of such a simulation are compared to the actual radiation loss obtained rigorously. It is shown that such a simulation cannot give reliable results concerning radiation loss from printed circuits. Author (revised)

SLOT-COUPLED PATCH ANTENNA WITH COPLANAR WAVEGUIDE FEED **c33**
Richard Q. Lee and Rainee N. Simons *In its* Solid State Technology Branch of NASA Lewis Research Center: Fifth Annual Digest Aug. 1993 p 89-92 Repr. from IEEE Antennas and Propagation Society International Symposium, Jul. 1992 p 1048-1051 (For primary document see N94-20497 05-32)
Avail: CASI HC A01/MF A03

Two slot-coupled feeding techniques for exciting a patch antenna with a coplanar waveguide (CPW) were experimentally investigated. In the first technique, a CPW with two notches on both sides of the slot lines is used to couple power to the antenna through a narrow rectangular slot. In the second technique, a grounded CPW with a series gap in the center strip conductor is used to couple power to the antenna through a 'dumbbell' slot. Results indicated that both techniques are feasible and yield high coupling efficiency.

Both ex situ and in situ spectroscopic ellipsometry (SE) measurements were employed to investigate the effects of HF cleaning on Si surfaces. The hydrogen-terminated (H-terminated) Si surface was modeled as an equivalent dielectric layer, and monitored in real time by SE measurements. The SE analyses indicate that after a 20-s 9:1 HF dip without rinse, the Si(100) surface was passivated by the hydrogen termination and remained chemically stable. Roughness of the HF-etched bare Si(100) surface was observed, in an ultrahigh vacuum (UHV) chamber, and analyzed by the in situ SE. Evidence for desorption of the H-terminated Si surface-layer, after being heated to approximately 550 C in the UHV chamber, is presented and discussed. This is the first use of an ex situ and in situ real-time, nondestructive technique capable of showing state of passivation, the rate of reoxidation, and the surface roughness of the H-terminated Si surfaces.

Avail: CASI HC A01/MF A03

An ellipsometric study of two Si(0.5)Ge(0.5)/Si strained-layer super lattices grown by MBE at low temperature (500 C) is presented, and results are compared with x ray diffraction (XRD) estimates. Excellent agreement is obtained between target values, XRD, and ellipsometry when one of two available Si(x)Ge(1-x) databases is used. It is shown that ellipsometry can be used to nondestructively determine the number of superlattice periods, layer thicknesses, Si(x)Ge(1-x) composition, and oxide thickness without resorting to additional sources of information. It was also noted that we do not observe any strain effect on the E(sub 1) critical point.

Spectroscopic ellipsometry (SE) was employed to characterize Si/Si(1-x)Ge(x) strained-layer superlattices. An algorithm was developed, using the available optical constants measured at a number of fixed x values of Ge composition, to compute the dielectric function spectrum of Si(1-x)Ge(x) at an arbitrary x value in the spectral range 17 to 5.6 eV. The ellipsometrically determined superlattice thicknesses and alloy compositional fractions were in excellent agreement with results from high-resolution x ray diffraction studies. The silicon surfaces of the superlattices were subjected to a 9:1 HF cleaning prior to the SE measurements. The HF solution removed silicon oxides on the semiconductor surface, and terminated the Si surface with hydrogen-silicon bonds, which were monitored over a period of several weeks, after the HF cleaning, by SE measurements. An equivalent dielectric layer model was established to describe the hydrogen-terminated Si surface layer. The passivated Si surface remained unchanged for greater than 2 h, and very little surface oxidation took place even over 3 to 4 days.

Due to the large size and the number of diffusion pumps, space simulation chambers cannot be easily calibrated by the usual test dome method for measuring backstreaming from oil diffusion pumps. In addition, location dependent contamination may be an important parameter of the test. The backstreaming contamination in the Space Power Facility (SPF) near Sandusky, Ohio, the largest space simulation vacuum test chamber in the U.S.A. was measured. Small size clean silicon wafers as contamination sensors placed at all desired measurement sites were used. The facility used diffusion pumps with DC 705 oil. The thickness of the contamination oil film was measured using ellipsometry. Since the oil did not wet uniformly the silicon substrate, two analysis models were developed to measure the oil film: continuous, homogeneous film and islands of oil with the islands varying in coverage fraction and height. In both cases, the contamination film refractive index was assumed to be that of DC 705. The second model improved the ellipsometric analysis quality parameter by up to two orders of magnitude, especially for the low coverage cases. Comparison of the two models for our case shows that the continuous film model overestimates the oil volume by less than 50 percent. Absolute numbers for backstreaming are in good agreement with published results for diffusion pumps. Good agreement was also found between the ellipsometric results and measurements done by x ray photoelectron spectroscopy (XPS) and by scanning electron microscopy (SEM) on samples exposed to the same vacuum runs. THE QUANTUM EFFICIENCY OF HgCdTe PHOTODIODES IN RELATION TO THE DIRECTION OF ILLUMINATION AND TO THEIR GEOMETRY **c33**

D. Rosenfeld and G. Bahir (Israel Inst. of Tech., Haifa.) *In its* Solid State Technology Branch of NASA Lewis Research Center: Fifth Annual Digest Aug. 1993 p 163-169 Repr. from American Inst. of Physics, Journal of Applied Physics, v. 72, no. 7, 1 Oct. 1992 (For primary document see N94-20497 05-32)
Avail: CASI HC A02/MF A03

A theoretical study of the effect of the direction of the incident light on the quantum efficiency of homogeneous HgCdTe photodiodes suitable for sensing infrared radiation in the 8-12 microns atmospheric window is presented. The probability of an excess minority carrier to reach the junction is derived as a function of its distance from the edge of the depletion region. Accordingly, the quantum efficiency of photodiodes is presented for two geometries. In the first, the light is introduced directly to the area in which it is absorbed (opaque region), while in the second, the light passes through a transparent region before it reaches the opaque region. Finally, the performance of the two types of diodes is analyzed with the objective of finding the optimal width of the absorption area. The quantum efficiency depends strongly on the way in which the light is introduced. The structure in which the radiation is absorbed following its crossing the transparent region is associated with both higher quantum efficiency and homogeneity. In addition, for absorption region widths higher than a certain minimum, the quantum efficiency in this case is insensitive to the width of the absorption region. Author (revised)

Since the discovery of high temperature superconductivity in 1987, NASA Lewis Research Center has been involved in efforts to demonstrate its advantages for applications involving microwave electronics in space, especially space communications. The program included thin film fabrication by means of laser ablation. Specific circuitry which was investigated includes microstrip ring resonators at 32 GHz, phase shifters which utilize a superconducting, optically activated switch, an 8x8 32 GHz superconducting microstrip antenna array, and an HTS-ring-resonator stabilized oscillator at 8 GHz. The latter two components are candidates for use in space experiments which are described in other papers. Experimental data on most of the circuits are presented as well as, in some cases, a comparison of their performance with an identical circuit utilizing gold or copper metallization. (Contract NCC3-197)
Avail: CASI HC A02/MF A03

YBa2Cu3O(7-delta) thin films were formed on NdGaO3 substrates by laser ablation. Critical temperatures greater than 89 K and critical current densities exceeding 2 x 10(exp 8) Acm(sub -2) at 77 K were obtained. The microwave performance of films patterned into microstrip ring resonators with gold ground planes was measured. An unloaded quality factor six times larger than that of a gold resonator of identical geometry was achieved. The unloaded quality factor decreased below 70 K for both the superconducting and gold resonators due to increasing dielectric losses in the substrate. The temperature dependence of the loss tangent of NdGaO3 was extracted from the measurements. Author (revised)

Avail: CASI HC A02/MF A03

Microwave properties of sputtered Tl-Ca-Ba-Cu-O thin films were investigated by designing, fabricating, and testing microstrip ring resonators. Ring resonators designed for 12 GHz fundamental resonance frequency, were fabricated and tested. From the unloaded Q values for the resonators, the surface resistance was calculated by separating the conductor losses from the total losses. The penetration depth was obtained from the temperature dependence of resonance frequency, assuming that the shift in resonance frequency is mainly due to the temperature dependence of penetration depth. The effective surface resistance at 12 GHz and 77 K was determined to be between 1.5 and 2.75 mOmega, almost an order lower than Cu at the same temperature and frequency. The effective penetration depth at 0 K is approximately 7000 A. Author (revised)

Bhasin *In its* Solid State Technology Branch of NASA Lewis Research Center: Fifth Annual Digest Aug. 1993 p 225-229 Repr. from IEEE Transactions on Applied Superconductivity, v. 3, no. 1, Mar. 1993 p 23-27 (For primary document see N94-20497 05-32)

Avail: CASI HC A01/MF A03

A 10 GHz hybrid Y-Ba-Cu-O / GaAs microwave oscillator proximity coupled to a circular microstrip antenna was designed, fabricated and characterized. The oscillator was a reflection mode type using a GaAs MESFET as the active element. The feedline, transmission lines, RF chokes, and bias lines were all fabricated from YBa2Cu3O(7-x) superconducting thin films on a 1 cm x 1 cm lanthanum aluminate substrate. The output feedline of the oscillator was wire bonded to a superconducting feedline on a second 1 cm x 1 cm lanthanum aluminate substrate, which was in turn proximity coupled to a circular microstrip patch antenna. Antenna patterns from this active patch antenna and the performance of the oscillator measured at 77 K are reported. The oscillator had a maximum output power of 11.5 dBm at 77 K, which corresponded to an efficiency of 10 percent. In addition, the efficiency of the microstrip patch antenna together with its high temperature superconducting feedline was measured from 85 K to 30 K and was found to be 71 percent at 77 4 increasing to a maximum of 87.4 percent at 30 K. MICROWAVE PROPERTIES AND CHARACTERIZATION OF CO-EVAPORATED BSCCO THIN FILMS **c27**

F. A. Miranda, C. M. Chorey (Sverdrup Technology, Inc., Brook Park, OH.), M. A. Stan (Kent State Univ., OH.), C. E. Nordgren (Case Western Reserve Univ., Cleveland, OH.), R. Y. Kwor (Colorado Univ., Colorado Springs.), and T. S. Kalkur (Colorado Univ., Colorado Springs.) *In its* Solid State Technology Branch of NASA Lewis Research Center: Fifth Annual Digest Aug. 1993 p 235-242 Repr. from U.S. Government, 1992 (For primary document see N94-20497 05-32)

Avail: CASI HC A02/MF A03

An extensive characterization of Bi-Sr-Ca-Cu-O (BSCCO) thin films deposited by co-evaporation on LaAlO3 and SrTiO3 substrates was performed. The films had a T(sub c) (R = O) of approximately 78 K, and were predominantly c-axis oriented, with critical current densities (J(sub c)) at 4.5 K of 1.6 x 10(exp 6) and 1.1 x 10(exp 6) A cm(sup -2), for the samples on SrTiO3 and LaAlO3, respectively. The microwave properties of the films were examined by three techniques. The complex conductivity sigma(sub *) = sigma(sub 1) - j(sigma(sub 2)) and the magnetic penetration depth (A) were measured by power transmission at 30.6 GHz; the surface resistance (R(sub s)) was measured using a cavity resonator at 58.9 GHz, and the transmission line losses were determined by measuring the quality factor (Q) of a linear microstrip resonator at 10.4 and 20.2 GHz. The complex conductivity for the film on LaAlO3 was determined to be (2.0-j10) x 10(exp 5) S/m at 77 K. It was observed that in the superconducting state sigma(sub 1) deviates from both the Bardeen-Cooper-Schrieffer (BCS) theory and the two-fluid model. Values of lambda were found to be approximately 2.0 and 1.1 microns at 77 K and 20 K respectively, and were obtained for the film on LaAlO3. The value of lambda at 20 K was approximately three times larger than that of BSCCO single crystals. R(sub s) values of 865 and 1391 mOmega were obtained for the films on SrTiO3 and LaAlO3, respectively, at 77 K and 58.9 GHz. Unloaded Q factors at 20 K of approximately 1100 and 800 at 10.4 and 20.2 GHz respectively, were measured for the BSCCO resonator. Unloaded Q values of 290 and 405 at 20 K were obtained at 10.4 GHz and 20.2 GHz respectively, for an all gold (Au) resonator. Author (revised)

(Grant NAG4-0751)

Avail: CASI HC A02/MF A03

The excess conductivity behavior of highly oriented YBa2Cu3O(7-x) thin films prepared by both coevaporation and laser ablation was studied in detail in the reduced-temperature range 9 x 10(exp -4) is less than t is less than 1. The excess conductivity in all the films studied was found to diverge sharply near T(sub c), in agreement with the conventional mean-field theory. However, the detailed temperature dependence could not be fitted to either the power-law or the logarithmic functional forms as predicted by the theory. The excess conductivity of all the films was found to be exponentially dependent on the temperature over nearly three decades for 9 x 10(exp -4) is less than t is less than 10(exp -1), in contradiction to the mean-field theory. SEGMENT-BASED ACOUSTIC MODELS FOR CONTINUOUS SPEECH RECOGNITION Progress Report, 1 Oct. 1992 - 30 Sep. 1993

Mari Ostendorf and J. R. Rohlicek 8 Oct. 1993 12 p

(Contract N00014-92-J-1778; NSF IRI-89-02124)

(AD-A271483) Avail: CASI HC A03/MF A01

This research aims to develop new and more accurate stochastic models for speaker-independent continuous speech recognition by extending previous work in segment-based modeling and by introducing a new hierarchical approach to representing intra-utterance statistical dependencies. These techniques, which have high computational costs because of the large search space associated with higher order models, are made feasible through rescoring a set of HMM-generated N-best sentence hypotheses. We expect these different modeling techniques to result in improved recognition performance over that achieved by current systems, which handle only frame-based observations and assume that these observations are independent given an underlying state sequence. AN INVERSE DWT FOR NONORTHOGONAL WAVELETS Final Report
M. J. Shensa Sep. 1993 58 p
(AD-A272064; NCCOSC/RDT/E-TR-1621) Avail: CASI HC A04/MF A01

Discrete nonorthogonal wavelet transforms play an important role in signal processing by offering finer resolution in time and scale than their orthogonal counterparts. The standard inversion procedure for such transforms is a finite expansion in terms of the analyzing wavelet. This approximation works quite well for many signals; however, for other signals, it fails to achieve good accuracy or requires an excessive number of scales. This paper proposes several algorithms that provide more adequate inversion and compares them in the case of Morlet wavelets. In the process, both practical and theoretical issues for the inversion of nonorthogonal wavelet transforms are discussed. DTIC

(Contract N00014-91-C-0234)
(AD-A272280) Avail: CASI HC A05/MF A01

A new method of code allocation in Code Division Multiple Access is proposed, based on partitioned information 'classes' (CDMA-IC), that is particularly efficient in meeting multicasting needs. Transmitters choose spreading codes based on the types of messages they are transmitting, and receivers listen to codes corresponding to the types of messages they are interested in. The performance of this approach can exceed that of both the traditional receiver-directed codes or broadcast codes in environments where there are several multicast groups (in which a given message is of interest to more than one node), or where it is difficult to know what types of messages (out of a fixed set of message types) a receiver is interested in at any particular time. Performance is further enhanced when receivers can simultaneously attempt to correlate multiple spreading codes. A broad theoretical framework was developed for the CDMA-IC concept and numerical results through simulation were obtained and compared to receiver-directed and broadcasting scenarios. DTIC

The optimization and analysis of a localization and message transmission satellite system is described. The system is named TAOS which consists of five satellites and ground stations. The ground information processing centers provide messages to the customers and/or the localization of information with the help of mobile terminals. In order to improve the system performance a value analysis is carried out. The main purposes of the optimization were: to schedule the operations of TAOS; to allow validation of technical and economic choices made; and to homogenize the understanding of the TAOS mission to the customers. The principles of spaceborne Synthetic Aperture Radar (SAR) are given. Its application in the maritime environment is discussed, with reference to several specific systems. The requirement for calibration is discussed. Some of the more advanced techniques expected to be incorporated in future missions are summarized. Spaceborne SAR is a potentially powerful sensor in the maritime environment. Its active nature imparts an all weather, 24 hour imaging capability, limited only by orbit and power supply constraints. It is able to image a variety of ocean phenomena, leading to a range of applications in several fields. ESA

HIGH FREQUENCY (HF) AND METEOR BURST COMMUNICATIONS IN A POLAR ENVIRONMENT Final Report
J. R. Katan 30 Sep. 1993 341 p
(AD-A271604; NUWC-NPT-TD-10375) Avail: CASI HC A15/MF A03

HF radio provides a low-cost, long-range communications alternative to satellite communication (SATCOM). In the polar environment, however, the frequent occurrence of dense sporadic E layers during summer in high-sunspot periods can prevent propagation in the HF band for the desired communications ranges. During solar storms, intense radiation may induce significant D-region absorption which further reduces the utility of HF radio. These phenomena cannot be defeated by the use of automatic link establishment (ALE) HF radio equipment because of the broadband nature of these effects. The use of VHF communication techniques, such as meteor scatter, provide a viable supplement to maintain connectivity when normal ALE HF radio is ineffective. This study combines the analysis of Scott Base Ionosonde data with computer predictions using A Stand-Alone Prediction Program (ASAPS) from the Australian Radio Prediction Service and IONCAP from the Institute for Telecommunications of the U.S. Department of Commerce to quantify the possibility of HF communications and suggest suitable radio system design parameters. Similarly, predictions of meteor burst (MF) link performance are provided for comparison with available measurements so that comparisons may be performed with actual link operations. Finally, an HF/VHF radio system design is envisioned to meet polar communications requirements and follow-on work to develop and verify design details is recommended. DTIC

PHASED ARRAY ANTENNA WITH COUPLERS IN SPATIAL FILTER ARRANGEMENT Patent
Alfred R. Lopez, inventor (to Hazeltine, Corp.) 18 Feb. 1992 49 p Filed 29 Dec. 1987
(CA-Patent-1,296,098; Int-Patent-Class-H01Q-3/34; CTN-93-60666)
Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

A lossless spatial filter is provided between the antenna input ports and the elements of an array antenna so that the effective element pattern associated with each input port is primarily within a selected angular region of space. The antenna elements are arranged along a predetermined path and each element is connected to only one output port of the spatial filter. A beam steering unit controls the direction of radiation and includes N phase shifters and means for controlling the phase shifters. Each phase shifter has an input port and an output port which is connected to only one input port of the spatial filter. The antenna also includes a supply means for supplying wave energy signals. The supply means includes a signal generator supplying a power divider having N output signal ports, each output port connected to only one phase shifter input port. In microwave landing systems, this invention provides a non-thinned or fully filled array which may be used to achieve linearity and minimize the field monitor distance for the glide path antenna. A synthesis procedure for a five level non-thinned spatial filter is included. Author (CISTI)

An antenna radome includes a dielectric member shaped to protect an antenna from environmental conditions, and a plurality of conductors fixed in relation to a major surface of the dielectric member in a predetermined pattern so that the member with the conductors provides a lower reflection coefficient to incident electromagnetic waves at the operating wavelength of the antenna than in the absence of the conductors. Means are provided for causing a desired heating current to flow through the conductors, thereby enabling sufficient heat to be generated in the dielectric member to de-ice the radome during severe weather conditions. A specific embodiment of the radome of the invention is described for use with an antenna of the type used in a microwave landing system. CISTI

DATA COMPRESSION BY USING WAVELET TRANSFORMS AND VECTOR QUANTIZATION M.S. Thesis
Alper Erdemir Jun. 1993 82 p
(AD-A272763) Avail: CASI HC A05/MF A01

This thesis proposes a new analysis/synthesis procedure for speech and image compression. The algorithm applies the discrete wavelet transform to subject data in order to obtain a set of multiresolution wavelet coefficients. The wavelet coefficients are then encoded by using the generalized Lloyd algorithm. The statistical properties of the wavelet coefficients are utilized to determine the number of resolution levels as well as the codebook size at each resolution level. Coding results show that the new procedure provides a significant improvement in the quality of the reproduced data. The tested data includes speech, image, and transient signals. DTIC

NAVSPASUR SENSOR SYSTEM DIGITAL SIGNAL PROCESSING RECEIVER. VOLUME 1: HARDWARE AND SOFTWARE OVERVIEW Final Report, Oct. 1990 - Jul. 1993
Carl J. Morris, Carolyn F. Bryant, Marilyn P. Earl, and Tamara A. Myers 30 Sep. 1993 50 p
(AD-A272899; NRL/FR/8154-93-9577-Vol-1) Avail: CASI HC A03/MF A01

This is a system description of the Naval Space Surveillance (NAVSPASUR) Sensor System Digital Signal Processing Receiver (DSPR). The NAVSPASUR system began as an advanced research project in June 1958, was commissioned as an operational Naval command in February 1961, and is operated by the Naval Space Surveillance Center (NSSC) in Dahlgren, Virginia. The DSPR is a real-time radar data acquisition and analysis system. Its function is to detect, with no prior information, all space objects whose orbits cross the continental United States and to compute their subsequent orbits. It provides vital satellite information in support of national defense mission objectives of space intelligence, satellite attack warning, satellite intercept support, and space mission support. This system description was prepared as part of a modernization program that has replaced DSPR hardware for which parts are no longer available. Volume 1 (NRL/FR/8154--93-9577) describes the DSPR system in terms of current operation and hardware and software environment. Functions of the major subsystems and the relationship between them are discussed. Volume 2 (NRL/FR/8154--93-9578) discusses the function and capabilities of software and hardware components of the subsystems that provide the digital functions of the DSPR. For each subsystem, individual software modules and hardware components used primarily by that subsystem are described. DTIC

ATC/PILOT VOICE COMMUNICATIONS: A SURVEY OF THE LITERATURE Final Report
O. Veronika Prinzo and Thomas W. Britton Nov. 1993 38 p
(DOT/FAA/AM-93/20) Avail: CASI HC A03/MF A01

The first radio-equipped control tower in the United States opened at the Cleveland Municipal Airport in 1930. From that time to the present, voice radio communications have played a primary role in air safety. Verbal communications in air traffic control (ATC) operations have been frequently cited as causal factors in operational errors and pilot deviations in the FAA Operational Error and Deviation System, the NASA Aviation Safety Reporting System (ASRS), and reports derived from government sponsored research projects. Collectively, the data provided by these programs indicate that communications constitute a significant problem for pilots and controllers. Although the communications problem was well known the research literature was fragmented, making it difficult to appreciate the various types of verbal communications problems that existed and their unique influence on the quality of ATC/pilot communications. This is a survey of the voice radio communications literature. The 43 reports in the review represent survey data, field studies, laboratory studies, narrative reports, and reviews. The survey topics pertain to communications taxonomies, acoustical correlates and cognitive/psycholinguistic perspectives. Communications taxonomies were used to identify the frequency and types of information that constitute routine communications, as well as those communications involved in operational errors, pilot deviations, and other safety-related events. Acoustical correlate methodologies identified some qualities of a speaker's voice, such as loudness, pitch, and speech rate, which might be used potentially to monitor stress, mental workload, and other forms of psychological or physiological factors that affect performance. Cognitive/psycho-linguistic research offered an information processing perspective for understanding how pilots' and controllers' memory and language comprehension processes affect their ability to communicate effectively with one another. This analysis of the ATC/pilot voice radio communications literature was performed to provide an organized summary for the systematic study of interactive communications between controllers and pilots. Recommendations are given for new research initiatives, communications-based instructional materials, and human factors applications for new communications systems. Author

USE OF THE WEISS-WEINSTEIN BOUND TO COMPARE THE DIRECTION-FINDING PERFORMANCE OF SPARSE ARRAYS Technical Report
D. F. DeLong 16 Aug. 1993 62 p

(Contract F19628-90-C-0002)
(AD-A272582; TR-982; ESC-TR-93-244) Avail: CASI HC A04/MF A01

Weiss and Weinstein have recently derived a new lower bound on random parameter estimation error. This bound is used to develop a criterion for comparing two sparse array configurations. The arrays are first adjusted in size so that their direction-finding (DF) accuracies at high element signal-to-noise ratio (ESNR) are the same when averaged over all possible directions of arrival in the hemisphere. Then their threshold ESNR's are calculated using the Weiss-Weinstein bound. The array having the lower threshold ESNR is judged the better array. As an example of the application of the bound, three 7-element arrays, a circle, a spiral, and an L-shaped array are compared. The bound is also extended to the case of switched subarrays, where data are collected from several subarrays sequentially in time and processed as a unit. The purpose is to achieve DF accuracy approaching that of the full array while reducing the number of signal processing channels. An example, using five receivers on the 7-element spiral array, shows that this is indeed possible. DTIC

A COMPACT, PORTABLE EHF/SHF ANTENNA FOR ADVANCED SCAMP Technical Report
Joseph C. Lee 22 Sep. 1993 59 p
(Contract F19628-90-C-0002)
(AD-A272614; TR-981; ESC-TR-93-211) Avail: CASI HC A04/MF A01

The small, single-channel, antijam, man-portable (SCAMP) terminal is used for extremely high frequency (EHF) satellite communication. Since its development in 1987, it has repeatedly demonstrated successful communication through the EHF packages on the FLTSAT-7 and -8 Navy communication satellites. Advanced SCAMP is the second generation small terminal, highly elevated in performance and significantly reduced in weight. It is currently being developed at Lincoln Laboratory. Pertinent parameters are its 30-lb total weight, 75- to 2,400-bps data rate, and 24-in antenna aperture. Starting with the basic dual-band feed developed for another application, a compact, high-performance, EHF, dual-band ring-focus feed with an elliptical subreflector was developed for a displaced axis parabolic reflector. This reflector is made up of six lightweight deployable petals for portability. The feed weighs less than 1 lb, and the reflector weights 2.6 lb. The measured added loss due to imperfections of the petal reflector for the 44.5- and 20.7-GHz bands are 0.3 and 0.1 dB, respectively. An overall antenna efficiency of about 65% and 55% in the Q- and K-bands was achieved. Antenna and feed design considerations, measured performance, and other possible applications for this antenna are discussed. DTIC

A NEW MATRIX FORMULATION OF CLASSICAL ELECTRODYNAMICS. PART 3: WAVE PROPAGATION THROUGH A MULTILAYER DIELECTRIC MEDIUM WITH PLANAR BOUNDARIES Final Report, period ending Sep. 1993
R. P. Bocker Oct. 1993 68 p
(AD-A271610; NCCOSC/RDT/E-TD-2569-Pt-3) Avail: CASI HC A04/MF A01

A new approach for solving electromagnetic wave propagation problems is currently being developed at the Naval Command, Control and Ocean Surveillance Center (NCCOSC), RDT and E Division (NRaD). This new approach is based upon an eight by eight matrix representation of the Maxwell field equations. In addition, a computer software package based on this matrix representation of electromagnetic theory is also being written and tested at NRaD to handle a variety of scenarios involving electromagnetic wave propagation through matter. This software package is referred to as the MATURE Program. MATURE is the acronym for matrix approach to understanding relativistic electrodynamics. The MATURE program is written in MATLAB code for use on a Sun 4 SPARCstation 2 workstation. Under Independent Research (IR) FY 92 funding, this matrix approach was successfully employed in solving problems dealing with electromagnetic wave propagation through dielectric, crystalline, linear electro-optic, and magneto-optic materials of infinite extent. Under the Office of Naval Research (ONR) FY 93 funding, this matrix formulation was extended to handle problems involving wave propagation through multilayer dielectric media with planar boundaries. Presented in this technical document is the underlying theory of this matrix approach. Several numerical examples, based on the use of the MATURE program, are also included to illustrate the use of the matrix approach in solving electromagnetic wave propagation problems. DTIC

DOWNLINK ACQUISITION AND TRACKING PROCEDURES FOR THE ASCAMP SATELLITE COMMUNICATIONS TERMINAL
Robert J. Figucia 14 Sep. 1993 58 p
(Contract F19628-90-C-0002)
(AD-A272912; ESC-TR-93-236) Avail: CASI HC A04/MF A01

The advanced single-channel antijam man portable (ASCAMP) terminal was developed at MIT Uncoin Laboratory as a proof of concept for the Army's SCAMP terminal. The ASCAMP terminal is a 30-lb, extremely high frequency (EHF) satellite communications terminal capable of operating from 75 to 2,400 bps with low inclination, geosynchronous FLTSAT EHF package and Milstar satellites. The terminal was designed to be carried, set up, and operated by a single user. In many instances the control algorithms were designed to compensate for simplifications made in the hardware to keep the terminal's size, weight, and power to a minimum. The procedures implemented in the ASCAMP terminal to locate the satellite and synchronize with its downlink are described. It contains descriptions of the timing and pointing requirements, the procedures for acquisition and tracking, and the measured performance. DTIC

MATHCAD COMPUTER APPLICATIONS PREDICTING ANTENNA PARAMETERS FROM ANTENNA PHYSICAL DIMENSIONS AND GROUND CHARACTERISTICS M.S. Thesis
Donald D. Gerry Jun. 1993 271 p
(AD-A272987) Avail: CASI HC A12/MF A03

This report provides the documentation for a set of computer applications for the evaluation of antenna parameters. The applications are written for the Mathcad personal computer software for various antenna types listed in the thesis index. Antenna dimensions and, in some cases, ground parameters are the only required inputs for each application. No new antenna parameter equations were developed as a part of this research. The chapters of this thesis are intended to provide Mathcad antenna application users with the background information necessary to readily use and interpret the software for each antenna type. Appendices are provided with examples of each antenna application. Each application has an introductory paragraph and a table of required inputs. The Mathcad software provides various numerical outputs and performance predictions, as well as a graphical representation of radiation patterns in the far-field. Mathcad application results are consistent with the predictions of applicable publications, as well as other antenna numerical analysis programs. DTIC

GOVERNMENT OPEN SYSTEMS INTERCONNECTION PROFILE (GOSIP) TRANSITION STRATEGY M.S. Thesis
Mark R. Laxen Sep. 1993 112 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273005) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis analyzes the Government Open Systems Interconnection Profile (GOSIP) and the requirements of the Federal Information Processing Standard (FIPS) Publication 146-1. It begins by examining the International Organization for Standardization (ISO) Open Systems Interconnection (OSI) architecture and protocol suites and the distinctions between GOSIP version one and two. Additionally, it explores some of the GOSIP protocol details and discusses the process by which standards organizations have developed their recommendations. Implementation considerations from both government and vendor perspectives illustrate the barriers and requirements faced by information systems managers, as well as basic transition strategies. The result of this thesis is to show a transition strategy through an extended and coordinated period of coexistence due to extensive legacy systems and GOSIP product unavailability. Recommendations for GOSIP protocol standards to include capabilities outside the OSI model are also presented. DTIC

TELECOMMUNICATIONS SERVICES FOR MULTIMEDIA DATA EXCHANGE SUPPORT M.S. Thesis
Paul C. Gibbons Jun. 1993 102 p
(AD-A271704) Avail: CASI HC A06/MF A02

Multimedia holds the promise of increased knowledge, creativity and productivity for virtually any application that can be imagined. The ability to present information in both an informative and entertaining way can lead to an enhanced quality of life for an increasingly larger segment of the world's population. However, information generated in a multimedia format presents special challenges for communication networks. This thesis is an attempt to understand the impact of multimedia computing as it relates to the transmission requirements to support large volume data exchange in a distributed computing environment. With a good understanding of these requirements one will be better equipped to evaluate the various physical transmission media and communication services available to meet the high transmission demands imposed by multimedia data exchange. (Contract MDA972-91-C-0028)
(AD-A272567) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Successful electrical testing was performed on 44,460 tip array. High-frequency testing is underway, both in-house and at Litton subprogram site. The first two runs of 2 microns column devices are finished. Arrays of 232,630 tips have been successfully fabricated and are being electrically tested. Two fabrication runs of 4 microns column devices have been started and are proceeding on a revised schedule after delays in the initial photolithography step. More rigorous uniformity requirements have resulted in modification of the initial photolithography steps. An in-situ cleaning system was installed and evaluated in the test chamber. Additional testing is needed to bring the cleaning process under control. Development of low work function and metal coatings has focused on the optimization of the deposition process for tantalum nitride, and the development of deposition processes for lanthanum hexaboride and zirconium carbide. The chemical composition, resistivity, and growth rate of the deposited films is being analyzed by several methods. A device serialization method was implemented to improve record keeping on field emitter device testing. DTIC

ELF COMMUNICATIONS SYSTEM ECOLOGICAL MONITORING PROGRAM Summary Report, 1982 - 1991
M. M. Abromavage Nov. 1992 107 p
(Contract N00039-88-C-0065)
(AD-A272507; IITRI-D06200-3) Avail: CASI HC A06/MF A02

The U.S. Navy initiated an ecological monitoring program in 1982 as a part of its environmental quality program for its extremely low frequency (ELF) radio transmitting stations in Wisconsin and Michigan. Investigators have completed and reported work each year through 1991. This report describes 13 projects comprising the ecological monitoring program and the findings through 1991. Studies in Wisconsin have been completed, with no indications that ecological relationships have been influenced by electromagnetic fields produced by the ELF radio transmitter in that state. Studies in Michigan are continuing. DTIC

MILITARY SATELLITE COMMUNICATIONS DECISION SUPPORT SYSTEM REQUIREMENTS ANALYSIS AND USER INTERFACE DESIGN M.S. Thesis
Hugh A. Henry Jun. 1993 88 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273047) Avail: CASI HC A05

This research analyzed and decomposed U.S. Space Command missions to determine the requirements of a Military Satellite Communications Decision Support System (MDSS). Alternative functional architectures for an MDSS were evaluated and a graphical user interface prototype was developed. MDSS system requirements were derived through the combined use of the method of Critical Success Factors and the Representations, Operations, Memory Aids, and Controls method. The 'sandwich' architecture was suggested as the most suitable functional architecture for MDSS development. The user interface prototype allowed potential MDSS users to gain an appreciation of the look and feel of a potential system so they could more precisely articulate their specific requirements to MDSS builders. HYBRID FINITE ELEMENT/WAVEGUIDE MODE ANALYSIS OF PASSIVE RF DEVICES Report, Jan. 1992 - Jan. 1993
Daniel T. McGrath Jul. 1993 88 p
(AF Proj. 2304)
(AD-A273074; RL-TR-93-130) Avail: CASI HC A05/MF A01

A numerical solution for time-harmonic electromagnetic fields in two-port passive radio frequency (RF) devices has been developed, implemented in a computer code, and validated. Vector finite elements are used to represent the fields in the device interior, and field continuity across waveguide apertures is enforced by matching the interior solution to a sum of waveguide modes. Consequently, the mesh may end at the aperture instead of extending into the waveguide. The report discusses the variational formulation and its reduction to a linear system using Galerkin's method. It describes the computer code, including its interface to commercial CAD software used for geometry generation. It presents validation results for waveguide

discontinuities, coaxial transitions, and microstrip circuits. They demonstrate that the method is an effective and versatile tool for predicting the performance of passive RF devices. DTIC

QPPM RECEIVER FOR FREE-SPACE LASER COMMUNICATIONS

J. M. Budinger, J. H. Mohamed, L. A. Nagy, P. J. Lizanich (Analex Corp., Brook Park, OH.), and D. J. Mortensen (Sverdrup Technology, Inc., Brook Park, OH.) Jan. 1994 12 p Proposed for presentation at the 15th International Communications Satellite Systems Conference, San Diego, CA, 28 Feb. - 3 Mar. 1994; sponsored by AIAA

(RTOP 506-72-21)

(NASA-TM-106424; E-8265; NAS 1.15:106424; AIAA Paper 94-1160) Avail: CASI HC A03/MF A01

A prototype receiver developed at NASA Lewis Research Center for direct detection and demodulation of quaternary pulse position modulated (QPPM) optical carriers is described. The receiver enables dual-channel communications at 325-Megabits per second (Mbps) per channel. The optical components of the prototype receiver are briefly described. The electronic components, comprising the analog signal conditioning, slot clock recovery, matched filter and maximum likelihood data recovery circuits are described in more detail. A novel digital symbol clock recovery technique is presented as an alternative to conventional analog methods. Simulated link degradations including noise and pointing-error induced amplitude variations are applied. The bit-error-rate performance of the electronic portion of the prototype receiver under varying optical signal-to-noise power ratios is found to be within 1.5-dB of theory. Implementation of the receiver as a hybrid of analog and digital application specific integrated circuits is planned. Author

AN INTEGRO-ALGEBRAIC EQUATION FOR HIGH FREQUENCY WAKE FIELDS IN A TUBE WITH SMOOTHLY VARYING RADIUS

R. L. Warnock Jan. 1993 8 p Presented at the Computational Accelerator Physics Conference CAP 1993, Pleasanton, CA, 22-26 Feb. 1993

(Contract DE-AC03-76SF-00515)

(DE93-040940; SU-SLAC-Pub-6038; CONF-930269-23) Avail: CASI HC A02/MF A01

A technique to find the longitudinal wake field at frequencies above or below the tube cut-off is described. The round tube is infinite in length, and has an arbitrary, smooth variation of radius over a finite interval. A system of integro-algebraic equations enforces the boundary conditions on the wall and the outgoing wave condition at infinity. The first step in an iterative solution of the system, valid for variations of tube radius with small derivative, yields a convenient formula for the impedance as a double integral. At low frequencies the formula gives Yokoya's result plus corrections that can be large. For high frequencies in the case of several wall undulations it gives a sequence of finite-Q resonances. To avoid the limitations of the iterative method, a numerical solution of the system is carried out. DOE

RADIATION AND SCATTERING FROM PRINTED ANTENNAS ON CYLINDRICALLY CONFORMAL PLATFORMS Final Report

Leo C. Kempel, John L. Volakis, and Sunil Bindiganavale Jan. 1994 115 p

(Grant NAG1-1478)

(NASA-CR-194703; NAS 1.26:194703; UM-030601-3-T) Avail: CASI HC A06/MF A02

The goal was to develop suitable methods and software for the analysis of antennas on cylindrical coated and uncoated platforms. Specifically, the finite element boundary integral and finite element ABC methods were employed successfully and associated software were developed for the analysis and design of wraparound and discrete cavity-backed arrays situated on cylindrical platforms. This work led to the successful implementation of analysis software for such antennas. Developments which played a role in this respect are the efficient implementation of the 3D Green's function for a metallic cylinder, the incorporation of the fast Fourier transform in computing the matrix-vector products executed in the solver of the finite element-boundary integral system, and the development of a new absorbing boundary condition for terminating the finite element mesh on cylindrical surfaces. For individual titles, see N94-21886 through N94-21888.

SCATTERING BY CAVITY-BACKED ANTENNAS ON A CIRCULAR CYLINDER

Leo C. Kempel and John L. Volakis *In its* Radiation and Scattering from Printed Antennas on Cylindrically Conformal Platforms Jan. 1994 p 1-35 (For primary document see N94-21885 05-32)

Avail: CASI HC A03/MF A02

Conformal arrays are popular antennas for aircraft, spacecraft, and land vehicle platforms due to their inherent low weight and drag properties. However, to date there has been a dearth of rigorous analytical or numerical solutions to aid the designer. In fact, it has been common practice to use limited measurements and planar approximations in designing such non-planar antennas. The finite element-boundary integral method is extended to scattering by cavity-backed structures in an infinite, metallic cylinder. In particular, the formulation specifics such as weight functions, dyadic Green's function, implementation details and particular difficulties inherent to cylindrical structures are discussed. Special care is taken to ensure that the resulting computer program has low memory demand and minimal computational requirements. Scattering results are presented and validated as much as possible. Author (revised)

RADIATION BY CAVITY-BACKED ANTENNAS ON A CIRCULAR CYLINDER

Leo C. Kempel, John L. Volakis, and Randy Sliva *In its* Radiation and Scattering from Printed Antennas on Cylindrically Conformal Platforms Jan. 1994 p 37-60 (For primary document see N94-21885 05-32)

Avail: CASI HC A03/MF A02

Conformal antenna arrays are popular antennas for aircraft, spacecraft and land vehicle platforms due to their inherent low weight, cost and drag properties. However, to date there has been a dearth of rigorous analytical or numerical solutions to aid the designer. In fact, it has been common practice to use limited measurements and planar approximations in designing such non-planar antennas. The finite element-boundary integral method is extended to radiation by cavity-backed structures in an infinite, metallic cylinder. The formulation is used to investigate the effect of cavity size on the radiation pattern for typical circumferentially and axially polarized patch antennas. Curvature effect on the gain, pattern shape, and input impedance is also studied. Finally, the accuracy of the FE-BI approach for a microstrip patch array is demonstrated. Author (revised)

USER MANUAL FOR EXCALIBUR: A FE-BI NUMERICAL LABORATORY FOR CAVITY-BACKED ANTENNAS IN A CIRCULAR CYLINDER, VERSION 1.2

Leo C. Kempel *In its* Radiation and Scattering from Printed Antennas on Cylindrically Conformal Platforms Jan. 1994 p 61-110 (For primary document see N94-21885 05-32)

Avail: CASI HC A03/MF A02

The Finite Element-Boundary Integral (FE-BI) technique was used to

analyze the scattering and radiation properties of cavity-backed patch antennas recessed in a metallic groundplane. A program, CAVITY3D, was written and found to yield accurate results for large arrays without the usual high memory and computational demand associated with competing formulations. Recently, the FE-BI approach was extended to cavity-backed antennas recessed in an infinite, metallic circular cylinder. EXCALIBUR is a computer program written in the Radiation Laboratory of the University of Michigan which implements this formulation. This user manual gives a brief introduction to EXCALIBUR and some hints as to its proper use. As with all computational electromagnetics programs (especially finite element programs), skilled use and best performance are only obtained through experience. However, several important aspects of the program such as portability, geometry generation, interpretation of results, and custom modification are addressed. Author (revised)

IMPROVED APPROXIMATE FORMULAS FOR FLUX FROM CYLINDRICAL AND RECTANGULAR SOURCES
O. J. Wallace and S. A. Bokharee Mar. 1993 66 p
(Contract DE-AC11-88PN-38014)
(DE93-011390; WAPD-TM-1623) Avail: CASI HC A04/MF A01

This report provides two new approximate formulas for the flux at detector points outside the radial and axial extensions of a homogeneous cylindrical source and improved approximate formulas for the flux at points opposite rectangular surface sources. These formulas extend the range of geometries for which analytic approximations may be used by shield design engineers to make rapid scoping studies and check more extensive calculations for reasonableness. These formulas can be used to support skeptical, independent evaluations and are also valuable teaching tools for introducing shield designers to complex shield analyses. NTIS

A MOTION EXTRACTION METHOD FOR SYNTHETIC APERTURE RADARS Ph.D. Thesis - Technische Univ.
[BEWEGUNGSEXTRAKTIONSVERFAHREN FUER RADAR MIT SYNTHETISCHER APERTUR]
Joao Roberto Moreira-Neto Sep. 1992 129 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by poor print
(DLR-FB-92-31; ETN-93-94456) Avail: Issuing Activity (European Space Agency (ESA)); DLR, Zentrale Allgemeine Dienste, Versand, Postfach 90 60 58, 5000 Cologne 90, Germany, HC

A new method for motion error extraction for synthetic aperture radars (SAR), which is proved theoretically and experimentally, is presented. The new technique, called reflectivity displacement method (RDM), analyzes the frequency shift between two ground reflectivity functions of adjacent and strongly overlapping azimuth power spectra. It extracts the radar sensor's forward velocity and the displacement in the line of sight direction. The RDM removes the need for complex and expensive inertial navigation systems and greatly simplifies the design of high resolution SAR systems. Examples are given in order to show numerous usability opportunities of RDM, such as mountain region, sea surfaces, and calibration of the SAR system in a turbulent atmosphere. ESA

A method for reconstructing the complex index of refraction of a bounded inhomogeneous object from measured scattered field data is presented. The index and the unknown fields within the object are simultaneously reconstructed in an iterative algorithm. The method is a refinement of earlier work which incorporates a more effective way to update the unknowns at each stage of the iteration. Considerable efficiency in the algorithm is achieved. Some numerical examples are given indicating the limits on the contrasts which can be reconstructed. These limits show that the range of contrasts that may be reconstructed is extended over that achievable with the earlier work. NTIS

CONTINUOUS-TIME DISCRETIZED-SPACE APPROACH TO MODELING SHORT-PULSE PROPAGATION AND SCATTERING
A. G. Tijhuis 1992 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-215259; ET/EM-1992-22) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

With the examples given in the paper, the author has described the building blocks for a new way of using integral equations to model the propagation and scattering of transient electromagnetic waves. Of each example, generalizations to more complicated scattering problems have already been realized. Mentioned in particular is the application of the marching-on in frequency method to the two dimensional transient scattering by conducting and dielectric obstacles. Applications to layered media include the excitation of a horizontally stratified dielectric slab by a point source and the excitation of a cylindrically symmetric borehole by a line or ring source. The next challenge is to combine these ideas so that realistic configurations can be handled. NTIS

(PB93-215275; ET/EM-1992-20) Copyright Avail: CASI HC A04

The basic equations of the electromagnetic field are summarized as far as they are needed in the theory of electromagnetic interference and shielding. Through the analysis of the planar electric current emitter, the propagation coefficient, attenuation coefficient, phase coefficient, wave-speed, wavelength, wave impedance, wave admittance, and power flow density of a wave are introduced. Next, the shielding effectiveness of a shielding plate and the shielding effectiveness of a shielding parallel-plate box are determined. In the latter, particular attention is given to the occurrence of internal resonance effects, which may degrade the shielding effectiveness. Further, a survey of some fundamental properties of a system of low frequency, multiconductor transmission lines is given. For a three conductor system with a plane of symmetry, the decomposition into the common mode and the differential mode of operation is discussed. Finally, expressions for the voltages and electric currents induced by external sources along a single transmission line are derived. NTIS

MODELLING SHORT BENT, GRADED INDEX DIELECTRIC SLAB WAVEGUIDES
Harrie J. M. Bastiaansen (PTT Research, Leidschendam, Netherlands.), Michiel V. D. Keur, and Hans Blok 3 Aug. 1992 37 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-215283; ET/EM-1992-19) Copyright Avail: CASI HC A03

Circularly short bent, graded index dielectric slab waveguides such as optical waveguides are mathematically modeled, using both a direct integration method and a source-type integral equation method. The former method is easy to implement, requiring only small amounts of computer time. The latter method has the possibility to be extended to a rigorous model for bent channel waveguides. Both homogeneous and inhomogeneous slab waveguide layers are considered. The mathematical models are validated through comparison of the numerical results with results obtained by the analytical resonance conditions. Numerous numerical examples are given. NTIS

The use of superhigh microwave frequencies for satellite communications has many advantages, but its major drawback lies in the effects of atmospheric hydrometeors on electromagnetic wave propagation. One research effort under way to investigate this problem is being conducted by the European Space Agency, which will launch the Olympus-1 communications satellite in June 1989. One of this satellite's four payloads is a 12.5/20/30 GHz beacon package which will enable 17 countries, including Canada, to conduct propagation experiments. The main objective of the Canadian participation is to study propagation during adverse weather conditions. The present thesis provides a model of the propagation path so that the system induced depolarization impurities can be removed from the received beacon signals. The overall system configuration and requirements are given. A system polarization matrix which incorporates all effects existing on the satellite link is described. Analyses needed to obtain the medium propagation characteristics from measured data at 12.5, 20, and 30 GHz are presented. The development of software to perform data acquisition and control of the equipment is reviewed and program listings are included. The preprocessing of the data using the mathematical model will be integrated into the software, as well as other needed mathematical analysis. Author (CISTI)

APERTURE COUPLING OF CIRCULAR CYLINDRICAL DIELECTRIC RESONATOR ANTENNA M.S. Thesis

Joseph Theodore H. St-Martin Sep. 1990 169 p

(ISBN-0-315-60632-0; CTN-94-60878) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A new dielectric resonator antenna (DRA) configuration is proposed, based on a circular cylindrical dielectric resonator which is electromagnetically coupled to a microstrip feedline via an aperture in the ground plane separating them. This structure is studied both theoretically and experimentally to establish its feasibility. The theoretical approach develops the equivalent circuit model for the entire structure. The electromagnetic fields present are considered using their modal expansion. The links between the modal coefficients for the fields in the various parts of the structure are determined by examining the physical situation at hand and applying the principle of reciprocity to a volume in the feedline below the aperture. The resonant frequency for a particular resonator size was estimated assuming perfect conduction surfaces. The DRA radiation pattern was calculated assuming an infinite ground plane and then using an effective circular ground plane with a finite diameter. Experimental measurements are presented in the 12-16 GHz range. The results establish that the structure resonates as expected, its input impedance can be matched in a number of ways, and its radiation pattern is generally as expected. Author (CISTI)

A FEASIBILITY STUDY OF A PARALLAX-BASED PASSIVE MISSILE APPROACH WARNING SYSTEM M.S. Thesis

Erik Ronning May 1990 177 p

(ISBN-0-315-60640-1; CTN-94-60879) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A classical technique for measuring range uses two telescopes separated on a baseline to allow their optical fields of view to be matched and the resulting parallax angle measured to yield range and azimuth. This technique has been transferred to a high speed signal processing system. Computer programs have been developed to calculate the range and azimuth of a target. Atmospheric effects, such as turbulence, contrast degradation, and forward scattering on a practical system are discussed along with adverse effects caused by vibrations. The feasibility of finding the range and azimuth of a target has been demonstrated over a range of 700 cm and 3.5 deg field of view for a wavelength of 632.8 nm and source power of 10 mW. Range and azimuth values acquired are accurate to within 5 percent. Similar results over longer ranges may be obtained. Author (CISTI)

Ground Penetrating Radar (GPR) is being used extensively during characterization and remediation of chemical and radioactive waste sites at the Hanford Site in Washington State. Time and money for GPR investigations are often not included during the planning and budgeting phase. Therefore GPR investigations must be inexpensive and quick to minimize impact on already established budgets and schedules. An approach to survey design, data collection, and interpretation has been developed which emphasizes speed and budget with minimal impact on the integrity of the interpretation or quality of the data. The following simple rules of thumb can be applied: (1) Assemble as much pre-survey information as possible, (2) Clearly define survey objectives prior to designing the survey and determine which combination of geophysical methods will best meet the objectives, (3) Continuously communicate with the client, before, during and after the investigation, (4) Only experienced GPR interpreters should acquire the field data, (5) Use real-time monitoring of the data to determine where and how much data to collect and assist in the interpretation, (6) Always 'error' in favor of collecting too much data, (7) Surveys should have closely spaced (preferably 5 feet, no more than 10 feet), orthogonal profiles, and (8) When possible, pull the antenna by hand. REAL-TIME STEP FREQUENCY RADAR M.S. Thesis

Chu Sunchun 1993 168 p

(ISBN-0-315-83588-5; CTN-94-60942) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Step frequency radar (SFR) offers advantages over impulse radar including better signal to noise ratio (SNR), better accuracy in locating targets composed of complex reflection coefficients, and flexibility. The slow processing speed of SFR has remained a major weakness of the system, imposing serious problems especially for airborne types of radar. A real-time SFR (RTSFR) design is proposed which can measure data at a rate of 30 Hz with 128 frequency steps. The RTSFR system is equivalent to an impulse radar that operates in the frequency domain. A series of ultrahigh frequency carrier waves that assemble a time domain impulse was transmitted. Each successive returned complex signal was coherently detected at an intermediate frequency of 200 kHz using a high speed digital phase detector. Collected data were then transmitted to the host computer for fast Fourier transform processing and display via a small computer systems interface bus. A software system was also developed which optimized the utilization of all available hardware using a parallel processing scheme. Program listings for the host and remote computers are included. The RTSFR exhibited a SNR of about 50 dB and was able to resolve targets that were 30 dB apart with the use of a Blackman window. Author (CISTI)

SPICE MACROMODEL FOR A 1-MEGAWATT POWER MOSFET SWITCH
C. Helms, M. Ackermann, T. Fischer, and M. Deveney 1993 13 p Presented at the 36th Midwest Symposium on Circuits and Systems, Detroit, MI, 16-18 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019415; SAND-93-0298C; CONF-930854-3) Avail: CASI HC A03/MF A01

This paper presents a SPICE macromodel for a 1-megawatt high power electrical switch which uses power MOSFET's as the active switching elements. The model accurately predicts the time dependent switching current and provides a reasonable representation of the time dependent switch resistance and voltage drop across the switch. Techniques for extracting model parameters for commercial power MOSFET's are discussed along with suggestions for extending the model to spark gaps and other high power switches. DOE

EFFECT OF EXCITON LOCALIZATION AND DELOCALIZATION ON MAGNETIC-FIELD-DEPENDENT PHOTOLUMINESCENCE LINEWIDTHS IN SEMICONDUCTORS
S. K. Lyo, E. D. Jones, and S. R. Kurtz 1993 9 p Presented at the 9th International Conference on Luminescence and Optical Spectroscopy of Condensed Matter, Storrs, CT, 9-13 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018860; SAND-93-0832C; CONF-930831-2) Avail: CASI HC A02/MF A01

Theory and data are presented for the photoluminescence linewidth in ordered and disordered semiconductor alloys (In(sub 0.48)Ga(sub 0.52)P) at low temperatures. In disordered (ordered) systems, the linewidth is due to exciton localization (exciton-impurity scattering) and increases (decreases) as a function of the field in agreement with the data. DOE

ADVANCED BATTERIES FOR ELECTRIC VEHICLE APPLICATIONS: NONTECHNICAL SUMMARY
G. L. Henriksen 1993 4 p Presented at the 206th American Chemical Society National Meeting, Chicago, IL, 22-27 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019007; ANL/CMT/CP-79201; CONF-930802-13) Avail: CASI HC A01/MF A01

This paper provides an overview of the performance characteristics of the most prominent batteries under development for electric vehicles (EV's) and compares these characteristics to the USABC Mid-Term and Long-Term criteria, as well as to typical vehicle-related battery requirements. Most of the battery performance information was obtained from independent tests, conducted using simulated driving power profiles, for DOE and EPRI at Argonne National Laboratory. The EV batteries are categorized as near-term, mid-term, and long-term technologies based on their relative development status, as well as our estimate of their potential availability as commercial EV batteries. Also, the performance capabilities generally increase in going from the near-term to the mid-term and on to the long-term technologies. To date, the USABC has chosen to fund a few selected mid-term and long-term battery technologies. Derived from text

PROCESS TO FABRICATE THICK COPLANAR MICROWAVE ELECTRODE STRUCTURES Patent Application
R. W. McElhanon, inventor (to Navy), G. K. Gopalakrishnan, inventor (to Navy), and W. K. Burns, inventor (to Navy) 18 Jun. 1993 19 p
(AD-D015913; US-Patent-Appl-SN-077903; Navy-Case-74654) Avail: CASI HC A03/MF A01

A process for making thick metal structures on a substrate has the steps of: selectively exposing a thick layer of photoresist disposed on a substrate to ultraviolet radiation including the 350 nm to 450 nm portion of the spectrum of a mercury vapor lamp, where the photoresist layer is a heat-treated and hydrated photoresist layer, to fully pattern the substrate; developing the patterned substrate by contacting the photoresist layer with a photoresist developing solution; exposing the photoresist layer to a plasma for hardening the pattern against thermal flow; hardbaking the photoresist pattern on the substrate; and plating the metal onto the patterned substrate using a low current density (J) during at least part of the plating process, making a thick metal structure on the substrate. CURRENT STATUS OF ENVIRONMENTAL, HEALTH, AND SAFETY ISSUES OF NICKEL METAL-HYDRIDE BATTERIES FOR ELECTRIC VEHICLES
D. Corbus, C. J. Hammel, and J. Mark Aug. 1993 87 p
(Contract DE-AC02-83CH-10093)
(DE93-017079; NREL/TP-463-5475) Avail: CASI HC A05/MF A01

This report identifies important environment, health, and safety issues associated with nickel metal-hydride (Ni-MH) batteries and assesses the need for further testing and analysis. Among the issues discussed are cell and battery safety, workplace health and safety, shipping requirements, and in-vehicle safety. The manufacture and recycling of Ni-MH batteries are also examined. This report also overviews the 'FH&S' issues associated with other nickel-based electric vehicle batteries; it examines venting characteristics, toxicity of battery materials, and the status of spent batteries as a hazardous waste. MODELING FAILURE AND RELIABILITY IN NEW-GENERATION DEVICES Final Report, 2 May 1990 - 1 May 1993
Jeffrey Frey 31 Jul. 1993 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-90-G-0120)
(AD-A271150; ARO-28004.1-EL) Avail: CASI HC A02

The physics of failure of semiconductor devices, and the means of simulating it, was studied in order to establish cost-effective methods to design two- and three-terminal semiconductor devices used in amplification, mixing, detection, and oscillation applications. An energy transport simulation code suitable for multi-layered two or three-terminal devices of Si, GaAs, and any other characterizable materials was written and its calculation speed continually enhanced using both physical approximation and numerical sophistication. Results were verified for submicronscale Si MOSFET's with hot-electron reliability problems and GaAs MESFET's with high-power microwave impingement problems. An effort to theoretically describe electron transport in hexagonal SiC and related crystals was also begun. DTIC

AUTOMATED HMC ASSEMBLY
R. J. Blazek Aug. 1993 43 p
(Contract DE-AC04-76DP-00613)
(DE93-040641; KCP-613-5079) Avail: CASI HC A03/MF A01

An automated gold wire bonder was characterized for bonding 1-mil gold wires to gallium arsenide (GaAs) monolithic microwave integrated circuits (MMIC's) which are used in microwave radar transmitter-receiver (T/R) modules. Acceptable gold wire bond test results were obtained for the fragile, 5-mil-thick GaAs MMIC's with gold-metallized bond pads; and average wire bond pull strengths, shear strengths, and failure modes were determined. An automated aluminum wire bonder was modified to be used as a gold wire bonder so that a wedge bond capability was available for GaAs MMIC's in addition to the gold ball bond capability. DOE

PROCEEDINGS OF THE 8TH INTERNATIONAL SYMPOSIUM ON APPLICATIONS OF FERROELECTRICS Final Report, 1 Jan. 1992 - 30 Jun. 1993
M. Liu, A. Safari, A. Kingon, and G. Haertling 1 Feb. 1993 658 p Symposium held in Greenville, SC, 30 Aug. - 2 Sep. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1474)
(AD-A270679) Avail: CASI HC A99

The eighth International Symposium on the Applications of Ferroelectrics was held in Greenville, SC, on August 30 to Sept 2, 1992. It was attended by approximately 260 scientists and engineers who presented nearly 200 oral and poster papers. The three plenary presentations covered ferroelectric materials which are currently moving into commercial exploitation or have strong potential to do so. These were (1) pyroelectric imaging, (2) ferroelectric materials integrated with silicon for use as micromotors and microsensors and (3) research activity in Japan on high permittivity materials for DRAM's. Invited papers covered such subjects as pyroelectric and electrooptic properties of thin films, photorefractive effects, ferroelectric polymers, piezoelectric transducers, processing of ferroelectrics, domain switching in ferroelectrics, thin film memories, thin film vacuum deposition techniques and the fabrication of chemically prepared PZT and PLZT thin films. The papers continued to reflect the large interest in ferroelectric thin films. It was encouraging that there have been substantial strides made in both the processing and understanding of the films in the last two years. It was equally clear, however, that much still remains to be done before reliable thin film devices will be available in the marketplace. DTIC

MEASURING LIQUID PROPERTIES WITH SMOOTH AND TEXTURED-SURFACE RESONATORS
S. J. Martin, K. O. Wessendorf, C. T. Gebert, G. C. Frye, R. W. Cernosek, L. Casaus, and M. A. Mitchell 1993 23 p Presented at the 1993 IEEE Frequency Control Symposium, Salt Lake City, UT, 2-4 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019433; SAND-93-1565C; CONF-9306205-2) Avail: CASI HC A03/MF A01

The sensitivity of quartz resonators to surface mass accumulation enables their use in a number of sensing applications. The linear change in resonant frequency that occurs with mass accumulation allows the device to function as a general-purpose gravimetric detector or 'microbalance.' The device is easily instrumented as a sensor by incorporating it as the frequency-control element of an oscillator circuit. The response of thickness shear mode (TSM) resonators in liquids is examined. Smooth-surface devices, which viscously entrain a layer of contacting liquid, respond to the product of liquid density and viscosity. Textured-surface devices, which also trap liquid in surface features, exhibit an additional response that depends on liquid density alone. Combining smooth and textured resonators in a monolithic sensor allows simultaneous measurement of liquid density and viscosity. DOE

VLSI DESIGN FOR RELIABILITY-CURRENT DENSITY Final Report, May 1991 - Sep. 1992
I. N. Hajj, P. Li, G. Kamath, G. Stamoulis, and H. Kriplani Jul. 1993 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F30602-91-C-0054)
(AD-A270719; RL-TR-93-129) Avail: CASI HC A03

This effort emphasizes the computation of the average and variance current density waveforms in the metal buses for estimating the mean time to failure (MTF) for electromigration effects. That effort is composed of two parts: the probabilistic simulation methods and software for computing the statistics of the current waveform at contact points to the buses, and the accurate extraction of the equivalent RC model of the bus for analyzing the bus currents. In addition, probabilistic methods have been applied to the calculation of the hot electron degradation in digital CMOS circuits and the problem of estimating the maximum current (as opposed to the average) in the bus for worst case voltage drop analysis. DTIC

LIGHTWEIGHT BATTERY ELECTRODE AND METHOD OF MAKING IT Patent
William A. Ferrando, inventor (to Navy) and Amarnath P. Divecha, inventor (to Navy) 30 Mar. 1993 8 p Filed 11 Jul. 1991
(AD-D015895; US-Patent-5,197,993; US-Patent-Appl-SN-728915; US-Patent-Class-29-2) Avail: US Patent and Trademark Office

A process for producing a lightweight electrode grid by exposing a heated mat of dense graphite fibers to Ni(CO)4 gas wherein the Ni(CO)4 decomposes upon contact with the graphite fibers depositing nickel metal coating on the graphic fibers is presented. The nickel coated graphite fibers are then sintered to form the grid. Nickel or cadmium electrodes are made by attaching a current collector to the grid and impregnating the grid with the appropriate nickel or cadmium active material. DTIC

EFFICIENT CHIP SIGNATURE CHECKING FOR DIAGNOSING BOUNDARY SCAN SYSTEMS
M. Lubaszewski, V. Castro-Alves, M. Nicolaidis, and B. Courtois Sep. 1992 22 p Sponsored in part by CAPES-COFECUB, Brazil
(RR-901-I; ETN-93-94991) Avail: CASI HC A03/MF A01

Off chip and on chip signature checking schemes suitable for Boundary Scan (BS) system testing are analyzed. The aim is to improve the diagnosis of onboard chip self testing at a negligible design effort. It is shown that an efficient off chip approach can reduce the memory requirements to store chip signatures. However, only a Built In Signature checking Circuit (BISC) can further improve diagnosis by reducing required memory and system scan time. Thus, based on the analysis of previous works and existing self checking approaches, the properties required for a BISC of general application are determined. A self testing BISC scheme which achieves these properties is proposed. The association of this BISC with an appropriate check of test data registers makes easier the task of embedding maximal diagnosis into a BS test controller chip. ESA

Described is an FET device for sensing a magnetic field, the FET device comprising: a semiconductor material having a source at a first position therein and receiving means at a second position therein for receiving charge carriers; bias voltage means for providing a bias voltage between the source and the receiving means to produce a movement of charge carriers between the source and the receiving means; a channel layer disposed within the semiconductor material between the source and the receiving means through which the charge carriers move as a function of the bias voltage and the magnetic field being sensed; a resistive gate disposed between the source and the receiving means and above the channel layer; a first resistive gate contact disposed in a first preselected position with respect to the source; a second resistive gate contact disposed in a second preselected position with respect to the receiving means; a resistive gate voltage means for providing a resistive gate bias voltage between the first and second resistive gate contacts to establish a longitudinal electric field in the channel layer; and output means disposed

in the semiconductor material for providing a signal related to the strength of the magnetic field sensed by the FET device. DTIC

A BREAKDOWN MODEL FOR THE BIPOLAR TRANSISTOR TO BE USED WITH CIRCUIT SIMULATORS
A. A. Keshavarz (Alliance Technologies Corp., Albuquerque, NM.), C. W. Raney, and D. C. Campbell 1993 22 p Presented at the 36th Midwest Symposium on Circuits and Systems, Detroit, MI, 16-18 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019422; SAND-93-0241C; CONF-930854-2) Avail: CASI HC A03/MF A01

A breakdown model for the output characteristics of the bipolar transistor (bjt) has been developed. The behavioral modeling capability of PSPICE, a popular SPICE program (with emphasis on integrated circuits) was used to implement the macromodel. The model predicts bjt output characteristics under breakdown conditions. Experimental data was obtained to verify the macromodel. Good agreement exists between the measured and the simulated results. DOE

CHARACTERIZATION AND POSSIBLE REPAIR OF DEFECTS IN SOFT X RAY PROJECTION LITHOGRAPHY MASKS
A. M. Hawryluk Jul. 1993 6 p Presented at the Optical Society of America Topical Meeting on Soft X Ray Projection Lithography, Monterey, CA, 10-12 May 1993
(Contract W-7405-eng-48)
(DE93-019147; UCRL-JC-114416; CONF-9305159-4) Avail: CASI HC A02/MF A01

Soft X-ray Projection Lithography (SXPL) is one promising technique for the mass production of integrated circuits with minimum feature sizes below 100 nm. Mask fabrication, inspection and repair processes are critically important to all forms of lithography, including SXPL which requires a reflection mask (a substrate coated with a x-ray multilayer coating and patterned with thin metallization layer). Processes for the repair of defects in the metallization patterns have been developed, but at present, there exist no processes for the repair of defects in the multilayer coatings deposited in LLNL's magnetron sputter deposition facility, which produces state of the art x-ray multilayer mirrors. We also propose one possible process for the repair of defects in these multilayer coatings. DOE

FUEL PROCESSING REQUIREMENTS AND TECHNIQUES FOR FUEL CELL PROPULSION POWER
R. Kumar, S. Ahmed, and M. Yu 1993 7 p Presented at the 206th American Chemical Society (ACS) National Meeting, Chicago, IL, 22-27 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019516; ANL/CMT/CP-79776; CONF-930802-9) Avail: CASI HC A02/MF A01

Fuels for fuel cells in transportation systems are likely to be methanol, natural gas, hydrogen, propane, or ethanol. Fuels other than hydrogen will need to be reformed to hydrogen on-board the vehicle. The fuel reformer must meet stringent requirements for weight and volume, product quality, and transient operation. It must be compact and lightweight, must produce low levels of CO and other byproducts, and must have rapid start-up and good dynamic response. Catalytic steam reforming, catalytic or noncatalytic partial oxidation reforming, or some combination of these processes may be used. This paper discusses salient features of the different kinds of reformers and describes the catalysts and processes being examined for the oxidation reforming of methanol and the steam reforming of ethanol. Effective catalysts and reaction conditions for the former have been identified; promising catalysts and reaction conditions for the latter are being investigated. DOE

PHOTOCONDUCTIVE SEMICONDUCTOR SWITCHES FOR PULSED POWER APPLICATIONS
G. M. Loubriel, F. J. Zutavern, G. J. Denison, W. D. Helgeson, D. L. McLaughlin, M. W. OMalley, and M. T. Buttram 1993 22 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019411; SAND-93-1630C; CONF-930616-31) Avail: CASI HC A03/MF A01

Photoconductive Semiconductor Switches (PCSS) are being used in, or tested for, many different pulsed power applications such as ultrawideband (UWB) transmitters and high current pulsers. Some aspects of the switches that are relevant to most of the applications are as follows: switch lifetime (longevity), switch opening time (related to the lifetime of carriers in the semiconductor), switching jitter, and the required laser energy. This paper will emphasize the results that we have obtained with Si switches for UWB applications. These include the following: measurement of switch longevity (a total of 80 Coulombs or 40 C/cm for a 2 cm wide switch and 18.4 Coulombs or 73 Coulombs/cm for a 0.25 cm wide switch), switching at high repetition rates (up to 540 Hz), measurement of carrier lifetime decay rates (a fast one of a few micro-s, and a slow one of about 330 micro-s), and measurements on the effect of neutron irradiation on carrier lifetimes. The total charge switched seems to be the highest ever reported for a PCSS. We have used these Si switches in a variety of circuits to produce: a monocycle with a period of about 10 ns corresponding to a center frequency of about 84 MHz, and ringing (many pulse) waveforms with periods of about 1 ns and 7.5 ns corresponding to center frequencies of 770 MHz and 133 MHz. We will also discuss recent studies on the switching properties of GaP. DOE

HIGH CURRENT DENSITY CONTACTS FOR PHOTOCONDUCTIVE SEMICONDUCTOR SWITCHES
A. G. Baca, H. P. Hjalmarson, G. M. Loubriel, D. L. McLaughlin, and F. J. Zutavern 1993 4 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract DE-AC04-76DP-00789)
(DE93-018837; SAND-93-1474C; CONF-930616-22) Avail: Issuing Activity (Department of Energy (DOE))

The current densities implied by current filaments in GaAs photoconductive semiconductor switches (PCSS) are in excess of 1 MA/cm(exp 2). As the lateral switches are tested repeatedly, damage accumulates at the contacts until electrical breakdown occurs across the surface of the insulating region. In order to improve the switch lifetime, the incorporation of n- and p-type ohmic contacts in lateral switches as well as surface geometry modifications are investigated. By using p-type AuBe ohmic contacts at the anode and n-type AuGe ohmic contacts at the cathode, contact lifetime improvements of 5-10x are observed compared to switches with n-type contacts at both anode and cathode. Failure analysis on samples operated for 1-1,000 shots show that extensive damage still exists for at least one contact on all switches observed and that temperatures approaching 500 C can be reached. However, the n-type AuGe cathode is often found to have no damage observable by scanning electron microscopy (SEM). The observed patterns of contact degradation indicate directions for future contact improvements in lateral switches. DOE

CsI AND SOME NEW PHOTOCATHODES
D. F. Anderson, S. Kwan, and V. Peskov Jun. 1993 19 p Presented at the 1st Workshop on RICH Detectors, Bari, Italy, 1-5 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-76CH-03000)
(DE93-019387; FNAL/C-93/128; CONF-9306188-2) Avail: CASI HC A03

A discussion of the possible sources of discrepancies in the measurements of the quantum efficiency of CsI photocathodes is presented. The authors propose that the major causes for disagreements in QE are due to the QE dependence on the current density extracted from the photocathode, on the electric field, and on the temperature of the photocathode. Preliminary results on TMAE enhanced GaAs and Si, plus TMAE protected CsTe and SbCs photocathodes, operated in gas, are also presented. DOE

KINETIC THEORY OF RUNAWAY AIR-BREAKDOWN
R. A. Roussel-Dupre (Los Alamos National Lab., NM.), A. V. Gurevich

(Academy of Sciences, USSR, Moscow.), T. Tunnell, and G. M. Milikh (Maryland Univ., College Park.) 1993 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC08-93NV-11265)
(DE93-040731; EGG-11265-5007) Avail: CASI HC A03

The kinetic theory for a new air breakdown mechanism advanced in a previous paper is developed. The relevant form of the Boltzmann equation is derived and the particle orbits in both velocity space and configuration space are computed. A numerical solution of the Boltzmann equation, assuming a spatially uniform electric field, is obtained and the temporal evolution of the electron velocity distribution function is described. The results of our analysis are used to estimate the magnitude of potential x-ray emissions from discharges in thunderstorms. DOE

LAYERED THIN-EDGED FIELD-EMITTER DEVICE Patent
Henry F. Gray, inventor (to Navy) 25 May 1993 10 p Filed 8 Jun. 1990
(AD-D015932; US-Patent-5,214,347; US-Patent-Appl-SN-535612; US-Patent-Class-313-355) Avail: US Patent and Trademark Office

A field-emitter-array device includes layers of conductive material and intervening layers of insulating material. The lateral edges of the layers form a field-emitter array including a field emitter edge electrode interposed between a pair of control electrodes. The control electrode edges produce an electric field causing the flow of field emitted electrons to be substantially parallel to the plane of the control and field emitter edge electrodes. The direction of electron flow can be further controlled by additional electrodes in the form of additional conductive layers or external electrodes. A process for making the emitter device includes forming a plurality of planar first and second layers of insulating material alternately disposed between first, second and third layers of conductive material, forming a channel through the thickness of the layers and oriented perpendicular thereto, exposing the lateral edges of the layers of conductive and insulating materials adjacent to the channel to form a field emitter edge electrode interposed between a pair of control electrodes. Additional electrodes may be provided to form and deflect the electron flow. DTIC

HIGH-POWER GAS SWITCH WITH HYDRIDE ELECTRODES Patent
R. K. Hutcherson, inventor (to Navy) and Stuart L. Moran, inventor (to Navy) 3 Aug. 1993 6 p Filed 6 Nov. 1991
(AD-D015956; US-Patent-5,233,143; US-Patent-Appl-SN-788660; US-Patent-Class-200-144) Avail: US Patent and Trademark Office

A high-power, high-repetition-rate spark gap switch having metal-hydride electrodes is provided. The spark gap switch is configured with a trigger and two electrodes fabricated with metal hydrides. The hydride metals may be selected from a variety of alloys including iron, nickel, magnesium, and palladium based alloys. Use of these alloys for fabrication of the electrodes permits hydrogen to be absorbed into the electrode material at a density approximately that of liquid hydrogen. During operation of the switch, the increasing temperature causes hydrogen to be desorbed into cavity surrounding the switch. Whereas the increasing temperature lowers the breakdown voltage of the switch, the increasing pressure raises the breakdown voltage. The result is that the switch operates at a constant breakdown voltage independent of temperature. DTIC

AN INVESTIGATION INTO THE INTEGRATION OF METER-LEVEL RANGE AND MILLIMETER-LEVEL PHASE DATA USING A MULTIMODE STIMULATION FOR OPTIMAL FILTER ESTIMATION SOFTWARE PACKAGE M.S. Thesis
Sharyn N. McWhorter Jun. 1993 140 p
(AD-A267955; AFIT/CI/CIA-93-115) Avail: CASI HC A07/MF A02

This is an investigation into the use of different types of Global Position System (GPS) data together with different types of bias sources. The intent was to examine their relative effect on the determination of the position of the receiver and the accuracy of the retrievable information. Selected inputs were processed through a simulation software package, Multimode Simulation for Optimal Filter Estimation (MSOF). GPS users and researchers continually attempt to analyze the effects of data and measurement biases to increase the quality of information gained from the system. Pseudorange and phase range data, together with various estimated and ignored measurement biases, were simulated and then processed through the optimal estimation software package. The output of the software-optimal estimations of the desired quantities provided insight into the consequence of virtually endless combinations of data.

TWO DIMENSIONAL SIMULATION OF THE ELECTRIC ARC BEHAVIOR IN A CUT-OFF DEVICE Ph.D. Thesis [SIMULATION BIDIMENSIONNELLE DU COMPORTEMENT D'UN ARC ELECTRIQUE DANS UN APPAREIL DE COUPURE]
Philippe Robin-Jouan 1992 189 p In FRENCH Original contains color illustrations
(ECL-92-41; ETN-93-94597) Avail: CASI HC A09/MF A02

The current cutoff in an electric circuit is followed by an electric arc between the contacts. The conducting media contains high intensity heat sources which induce very high temperature regions limited by boundaries of large temperature differences. Experimental tests are very hard to carry out under these conditions and simulations are needed. In order to perform the aerothermodynamic modeling, the dynamic, thermal, radiative, and electric effects have to be taken into account. A two dimensional calculation is performed by using parameters due to the influence of the wall at the horizontal surface between both electrodes. A thermal approach was applied and the importance of radiative parameters was stressed. The modeling of an electric arc was possible only for very short time delays and their strong dependence on magnetic forces was evidenced. Different front shapes, related to the structures of flow which form vortices, were characterized. ESA

AN 85 GHz QUASIOPTICAL GYROKLYSTRON EXPERIMENT Interim Report
Richard P. Fischer, Arne W. Fliflet, and Wallace M. Manheimer 29 Oct. 1993 197 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272020; NRL/MR/6793-93-7387) Avail: CASI HC A09

The design and test of a new type of millimeter-wave tube called a quasioptical gyroklystron is reported. The device comprises a pair of quasioptical resonators separated by a drift region, which is powered by an annular electron beam with typical parameters 75 kV beam voltage, 6 A current, and an electron pitch angle of 1.9. The gyroklystron is operated as a free-running oscillator, a mode-primed oscillator, an amplifier, and a phase-locked oscillator. The output resonator is tilted by 2 deg relative to the plane perpendicular to the electron beam axis, which is predicted to increase the efficiency and operating region of stable, single-mode operation. Experimental measurements indicate that the output is single-moded over nearly all the gyroklystron operating parameter space. A new regime of operation has been studied called alpha priming, where the electron beam parameters are ramped to obtain higher power and efficiency. Peak electronic efficiencies of 22% are measured in a single mode with peak output powers up to 150 kW at 85.5 GHz in 13 microsecond pulses. A depressed collector is added to the experiment to increase the overall efficiency of

the tube to greater than 30%. Capacitive probes in the drift tube are used to measure the average pitch angle of the beam electrons and the results are compared to electron trajectory simulations. Experimental measurements of the output radiation are compared to time-dependent, multimode computer simulations, which demonstrate the advantages of mode priming by prebunching the electron beam and alpha priming. (NLR-TP-91001-U; ETN-93-94335) Avail: CASI HC A04/MF A01

The NLR Infrastructure for Computer Aided Engineering (CAE) of Electronics (NICE) was introduced to solve problems due to the fact that CAE tools generally do not match mutually, with a view to the development of information systems for aerospace applications in which advanced electronics play an important role. CAE is used more and more to improve quality and reduce development time. Because most CAE tools generally do not match mutually, it is difficult to manage the design information present in the various tools and to exchange this information. NICE is based on an integrated set of local area networks, connected to the NLR computer network facilities. This is a basis for adding new tools for circuit simulation and analysis. Improved access to the tools and to the design information leads toward shorter development cycles of advanced electronics. ESA

Miller, and Pen-Shu Yeh *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 16 p (For primary document see N94-21079 05-33)
(Grant NAGw-3292)
Avail: CASI HC A03/MF A06

This paper first provides an overview of an adaptive, lossless, data compression algorithm originally devised by Rice in the early '70s. It then reports the development of a VLSI encoder/decoder chip set developed which implements this algorithm. A recent effort in making a space qualified version of the encoder is described along with several enhancements to the algorithm. The performance of the enhanced algorithm is compared with those from other currently available lossless compression techniques on multiple sets of test data. The results favor our implemented technique in many applications. Author

AVOIDING AND TOLERATING LATENCY IN LARGE-SCALE NEXT-GENERATION SHARED-MEMORY MULTIPROCESSORS **c62**
David K. Probst *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 15 p Sponsored in part by MicroNet (For primary document see N94-21079 05-33)
(Grants NSERC-A3363; NSERC-MEF-0040121)
Avail: CASI HC A03/MF A06

A scalable solution to the memory-latency problem is necessary to prevent the large latencies of synchronization and memory operations inherent in large-scale shared-memory multiprocessors from reducing high performance. We distinguish latency avoidance and latency tolerance. Latency is avoided when data is brought to nearby locales for future reference. Latency is tolerated when references are overlapped with other computation. Latency-avoiding locales include: processor registers, data caches used temporally, and nearby memory modules. Tolerating communication latency requires parallelism, allowing the overlap of communication and computation. Latency-tolerating techniques include: vector pipelining, data caches used spatially, prefetching in various forms, and multithreading in various forms. Relaxing the consistency model permits increased use of avoidance and tolerance techniques. Each model is a mapping from the program text to sets of partial orders on program operations; it is a convention about which temporal precedences among program operations are necessary. Information about temporal locality and parallelism constrains the use of avoidance and tolerance techniques. Suitable architectural primitives and compiler technology are required to exploit the increased freedom to reorder and overlap operations in relaxed models. Author

DESIGN OF CMOS LOGIC GATES FOR TID RADIATION
John Okyere Attia and Maria L. Sasabo *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p (For primary document see N94-21079 05-33)
(Grant NAG9-337)
Avail: CASI HC A02/MF A06

The rise time, fall time and propagation delay of the logic gates were derived. The effects of total ionizing dose (TID) radiation on the fall and rise times of CMOS logic gates were obtained using C program calculations and PSPICE simulations. The variations of mobility and threshold voltage on MOSFET transistors when subjected to TID radiation were used to determine the dependence of switching times on TID. The results of this work indicate that by increasing the size of P-channel transistor with respect to the N-channel transistors of the CMOS gates, the propagation delay of CMOS logic gate can be made to decrease with, or be independent of an increase in TID radiation. COMPARISON OF SINGLE EVENT UPSET RATES FOR MICROELECTRONIC MEMORY DEVICES DURING INTERPLANETARY SOLAR PARTICLE EVENTS c92
P. L. McKerracher, J. D. Kinnison, and R. H. Maurer *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 13 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

Variability in the methods and models used for single event upset calculations in microelectronic memory devices can lead to a range of possible upset rates. Using heavy ion and proton data for selected DRAM and SRAM memories, we have calculated an array of upset rates in order to compare the Adams worst case interplanetary solar flare model to a model proposed by scientists at the Jet Propulsion Laboratory. In addition, methods of upset rate calculation are compared: the Cosmic Ray Effects on Microelectronics CREME code and a Monte Carlo algorithm developed at the Applied Physics Laboratory. The results show that use of a more realistic, although still conservative, model of the space environment can have significant cost saving benefits. Author

STRV RADMON: AN INTEGRATED HIGH-ENERGY PARTICLE DETECTOR c19
Martin Buehler, George Soli, Brent Blaes, and Gemma Tardio *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

The RADMON (Radiation Monitor) was developed as a compact device with a 4-kbit SRAM particle detector and two p-FET total dose monitors. Thus it can be used as a spacecraft radiation alarm and in situ total dose monitor. This paper discusses the design and calibration of the SRAM for proton, alpha, and heavy ion detection. Upset rates for the RADMON, based on a newly developed space particle flux algorithm, are shown to vary over eight orders of magnitude. On the STRV (Space Technology Research Vehicle) the RADMON's SRAM will be used to detect trapped protons, solar flares, and cosmic rays and to evaluate our ability to predict space results from ground tests. SPACE QUALIFIED HIGH SPEED REED SOLOMON ENCODER c60
Jody W. Gambles (New Mexico Univ., Albuquerque.) and Tom Winkert *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p (For primary document see N94-21079 05-33)
Avail: CASI HC A02/MF A06

This paper reports a Class S CCSDS recommendation Reed Solomon encoder circuit baselined for several NASA programs. The chip is fabricated using United Technologies Microelectronics Center's UTE-R radiation-hardened gate array family, contains 64,000 p-n transistor pairs, and operates at a sustained output data rate of 200 MBits/s. The chip features a pin selectable message interleave depth of from 1 to 8 and supports output block lengths of 33 to 255 bytes. The UTE-R process is reported to produce parts that are radiation hardened to 16 Rads (Si) total dose and 1.0(exp -10) errors/bit-day. Author

Avail: CASI HC A02/MF A06

The need for large capacity, high speed mass memory storage devices has become increasingly evident at NASA during the past decade. High performance mass storage systems are crucial to present and future NASA systems. Spaceborne data storage system requirements have grown in response to the increasing amounts of data generated and processed by orbiting scientific experiments. Predictions indicate increases in the volume of data by orders of magnitude during the next decade. Current predictions are for storage capacities on the order of terabits (Tb), with data rates exceeding one gigabit per second (Gbps). As part of the design effort for a state of the art mass storage system, NASA Langley has designed a 144 CMOS ASIC to support high speed data transfers. This paper discusses the system architecture, ASIC design and some of the lessons learned in the development process. Author

MONGOOSE: CREATION OF A RAD-HARD MIPS R3000 c60
Dan Lincoln (LSI Logic Corp., Milpitas, CA.) and Brian Smith *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p (For primary document see N94-21079 05-33)
Avail: CASI HC A02/MF A06

This paper describes the development of a 32 Bit, full MIPS R3000 code-compatible Rad-Hard CPU, code named Mongoose. Mongoose progressed from contract award, through the design cycle, to operational

silicon in 12 months to meet a space mission for NASA. The goal was the creation of a fully static device capable of operation to the maximum Mil-883 derated speed, worst-case post-rad exposure with full operational integrity. This included consideration of features for functional enhancements relating to mission compatibility and removal of commercial practices not supported by Rad-Hard technology. 'Mongoose' developed from an evolution of LSI Logic's MIPS-I embedded processor, LR33000, code named Cobra, to its Rad-Hard 'equivalent', Mongoose. The term 'equivalent' is used to infer that the core of the processor is functionally identical, allowing the same use and optimizations of the MIPS-I Instruction Set software tool suite for compilation, software program trace, etc. This activity was started in September of 1991 under a contract from NASA-Goddard Space Flight Center (GSFC)-Flight Data Systems. The approach affected a teaming of NASA-GSFC for program development, LSI Logic for system and ASIC design coupled with the Rad-Hard process technology, and Harris (GASD) for Rad-Hard microprocessor design expertise. The program culminated with the generation of Rad-Hard Mongoose prototypes one year later.

DIGITAL RECEIVER FOR ON-BOARD FM/FSK-FM/BPSK DEMODULATION **c32**

G. Boscagli, M. C. Comparini, and M. Martone *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 13 p (For primary document see N94-21079 05-33)

Avail: CASI HC A03/MF A06

An all-digital demodulator FM/FSK-FM/BPSK is presented. The proposed architecture allows the 1-bit IF down-sampling technique with the hardware simplification of receiver analog section. The receiver exhibits great flexibility both in terms of signal demodulation (FSK or BPSK, subcarrier/ tone frequency, data rate) and interface capability. The demodulator is going to be realized in a VLSI chip (20 Kgate complexity). This paper describes the demodulator structure and its demodulation performances obtained with a breadboard based on programmable logic devices. The choice of a simple and effective scheme for frequency detection (FM and FSK demodulators) is suggested by system design considerations as well. Signal processing algorithms include also a Costas carrier phase recovery scheme in the case of BPSK signal and data transition tracking loop for the bit clock recovery. Test results address this solution as one of the most suitable for TT&C space application. Author

Avail: CASI HC A03/MF A06

The emerging digital audio and video compression technology brings both an opportunity and a new challenge to IC design. The pervasive application of compression technology to consumer electronics will require high volume, low cost IC's and fast time to market of the prototypes and production units. At the same time, the algorithms used in the compression technology result in complex VLSI IC's. The conflicting challenges of algorithm complexity, low cost, and fast time to market have an impact on device architecture and design methodology. The work presented in this paper is about the design of a dedicated, high precision, Motion Picture Expert Group (MPEG) audio decoder. Author (revised)

NATURE'S CRUCIBLE: MANUFACTURING OPTICAL NONLINEARITIES FOR HIGH RESOLUTION, HIGH SENSITIVITY ENCODING IN THE COMPOUND EYE OF THE FLY, MUSCA DOMESTICA **c74**

Mike Wilcox *In its* The Fifth NASA Symposium on VLSI Design 1993 14 p (For primary document see N94-21079 05-33)

Avail: CASI HC A03/MF A06

The number of pixels per unit area sampling an image determines Nyquist resolution. Therefore, the highest pixel density is the goal. Unfortunately, as reduction in pixel size approaches the wavelength of light, sensitivity is lost and noise increases. Animals face the same problems and have achieved novel solutions. Emulating these solutions offers potentially unlimited sensitivity with detector size approaching the diffraction limit. Once an image is 'captured', cellular preprocessing of information allows extraction of high resolution information from the scene. Computer simulation of this system promises hyperacuity for machine vision.

POWER OPTIMIZATION IN LOGIC ISOMERS **c60**
Ramesh Panwar (California Univ., Los Angeles.), David Rennels (California Univ., Los Angeles.), and Leon Alkalaj *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
(Contract N00014-91-J-1009)
Avail: CASI HC A03/MF A06

Logic isomers are labeled, 2-isomorphic graphs that implement the same logic function. Logic isomers may have significantly different power requirements even though they have the same number of transistors in the implementation. The power requirements of the isomers depend on the transition activity of the input signals. The power requirements of isomorphic graph isomers of n-input NAND and NOR gates are shown. Choosing the less power-consuming isomer instead of the others can yield significant power savings. Experimental results on a ripple-carry adder are presented to show that the implementation using the least power-consuming isomers requires approximately 10 percent less power than the implementation using the most power-consuming isomers. Simulations of other random logic designs also confirm that designs using less power-consuming isomers can reduce the logic power demand by approximately 10 percent as compared to designs using more power-consuming isomers. COMPUTATION OF SIGNAL DELAYS IN RC NETWORKS **c32**
Juan Carlos Hidalgo, Paliath Narendran, and Seth Chaiken *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

A model for signal delay computation in RC networks is presented. The strength of the paradigm is its generality and simplicity. The definition of delay is applicable to RC meshes with potential resistive attenuating paths to ground. The algorithms can also be applied to undriven circuits (static charge sharing) and circuits with initial charge. To compute the delays, each node in the network is explored locally to derive a system of sparse linear equations. The solutions of the system are delay values based on the Elmore time constant at each point in the circuit. Author (revised)

DELAY ANALYSIS OF COMBINATIONS OF PASS TRANSISTORS AND CLASSICAL LOGIC GATES
Jonathan S. Gibson *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

Combinations of pass transistors and logic gates driving nonlinear capacitive loads are analyzed for the presence of characteristics that will permit easier and more accurate digital logic simulation. Accurate time delay models are developed by studying the nature of the response of simplified circuit models to variations of input waveform rise and fall times and output loading. The nonlinear effects of the CMOS logic devices are minimized to permit easier interpretation of the influence of nonlinear capacitive loads. The performance of a CMOS inverter with a complex nonlinear load consisting of a pass transistor that separates a range of capacitances is compared to the same inverter circuit with a linear capacitive load to develop an understanding of the unique requirements of modeling a nonlinear system. Several methods of modeling the delay of CMOS circuits are reviewed, and a multi-parameter linear model is described. General guidelines for designing CMOS circuits with complex load circuits are developed, emphasizing that the circuit output rise delays and fall delays must be separately analyzed. Author

(Contract N00014-91-J-1009)
Avail: CASI HC A03/MF A06

A technique for minimizing the power dissipated in a Very Large Scale Integration (VLSI) chip by lowering the operating voltage without any significant penalty in the chip throughput even though low voltage operation results in slower circuits. Since the overall throughput of a VLSI chip depends on the speed of the critical path(s) in the chip, it may be possible to sustain the throughput rates attained at higher voltages by operating the circuits in the critical path(s) with a high voltage while operating the other circuits with a lower voltage to minimize the power dissipation. The interface between the gates which operate at different voltages is crucial for low power dissipation since the interface may possibly have high static current dissipation thus negating the gains of the low voltage operation. The design of a voltage level translator which does the interface between the low voltage and high voltage circuits without any significant static dissipation is presented. Then, the results of the mixed voltage design using a greedy algorithm on three chips for various operating voltages are presented. Author (revised)

FAULTY BEHAVIOR OF ASYNCHRONOUS STORAGE ELEMENTS

Waleed K. Al-Assadi, Ding Lu, Anura P. Jayasumana, Yashwant K. Malaiya, and Carol Q. Tong *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p Sponsored in part by Strategic Defense Initiative Organization (For primary document see N94-21079 05-33)

Avail: CASI HC A02/MF A06

It is often assumed that the faults in storage elements (SE's) can be modeled as output/input stuck-at-faults of the element. They are implicitly considered equivalent to the stuck-at faults in the combinational logic surrounding the SE cells. A more accurate higher level fault model for elementary SE's used in asynchronous circuits is presented. This model offers better representation of the physical failures. It is shown that the stuck-at model may be adequate if only modest fault coverage is desired. The enhanced model includes some common fault behaviors of SE's that are not covered by the stuck-at model. These include data-feed-through behaviors that cause the SE to be combinational. Fault models for complex SE cells can be obtained without a significant loss of information about the structure of the circuit. Author (revised)

TESTING SELF-TIMED CIRCUITS USING SCAN PATHS

Ajay Khoche and Erik L. Brunvand *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)

Avail: CASI HC A03/MF A06

Testing is an essential part of any digital system design and one that can be made much easier if testing is considered during the design process rather than after the system is complete. There are a number of techniques for integrating testability into system design, but many of these traditional testing methods used for synchronous circuits are not directly applicable to non-clocked asynchronous circuits. As a result, many asynchronous circuits do not employ design for testability techniques. A method of using the familiar model of scan paths modified to test self-timed systems are presented. Specifically, circuits designed using a library of self-timed modules to assemble systems with two-phase transition control and bundled data paths are considered. The method involves modifying these self-timed modules such that circuits designed from them have a built-in scan path. Author (revised)

DETECTION OF CMOS BRIDGING FAULTS USING MINIMAL STUCK-AT FAULT TEST SETS

Nabeel Ijaz and James F. Frenzel *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 10 p (For primary document see N94-21079 05-33)

Avail: CASI HC A02/MF A06

The performance of minimal stuck-at fault test sets at detecting bridging faults are evaluated. New functional models of circuit primitives are presented which allow accurate representation of bridging faults under switch-level simulation. The effectiveness of the patterns is evaluated using both voltage and current testing. Author (revised)

ROBUST NEURAL CLASSIFIER CIRCUITS USING ASYNCHRONOUS DESIGN

John F. Hurdle, Peter R. Conwell, and Erik L. Brunvand *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)

Avail: CASI HC A03/MF A06

Aerospace neural circuits must be adaptive, offer a practical size-performance ratio, and be environmentally robust. Our approach to building such circuits combines asynchronous design with a new fuzzy/neural classifier model. Asynchronous circuits offer many design advantages for neural hardware and our hybrid fuzzy/neural model, using mainly min and max operators, promises a low circuit complexity. The general approach is described and a description of a use of rule-induction to further reduce circuit complexity is described. Author (revised)

MULTIPLE-FOLD CLUSTERED PROCESSOR MESH ARRAY

Gerald G. Pechanek, Stamatis Vassiliadis (International Business Machines Corp., Endicott, NY.), and Jose G. Delgado (State Univ. of New York, Binghamton.) *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)

Avail: CASI HC A03/MF A06

The multiple-fold clustered processor mesh array is a triangular organization of clustered processing elements. This multiple-fold array maintains functional equivalence to the nearest neighbor mesh computer with uni-directional interprocessor communications, but with half the number of connection wires. In addition, the connectivity of the multiple-folded organization is superior to the standard square mesh due to the improved connectivity between the clustered processors. One of the primary application areas targeted is High Performance Architectures for image processing. Author

PRACTICAL ISSUES IN IMPLEMENTING ROVING SPARES IN VLSI SYSTOLIC ARRAYS
Rajendra Bandekar and Amitava Majumdar *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 12 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

In this paper we address several unsolved problems in implementing roving spares as a methodology for on-line testing and reconfiguration of systolic arrays. An algorithm for distinguishing between permanent faults and intermittent/transient faults is proposed. A methodology for determining different parameter values for this algorithm is presented. Results characterizing an optimal switching structure are presented. A judicious partitioning of information (for distributed and central processing) allows design of simple switch controllers for implementing roving spares operation as well as reconfiguration in the presence of failures. Testability and self-checking capability is incorporated into these controllers using a few extra gates. Author (revised)

A NOVEL VLSI PROCESSOR ARCHITECTURE FOR SUPERCOMPUTING ARRAYS **c60**
N. Venkateswaran, S. Pattabiraman, R. Devanathan, Ashaf Ahmed, S. Venkataraman, and N. Ganesh *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

Design of the processor element for general purpose massively parallel supercomputing arrays is highly complex and cost ineffective. To overcome this, the architecture and organization of the functional units of the processor element should be such as to suit the diverse computational structures and simplify mapping of complex communication structures of different classes of algorithms. This demands that the computation and communication structures of different class of algorithms be unified. While unifying the different communication structures is a difficult process, analysis of a wide class of algorithms reveals that their computation structures can be expressed in terms of basic IP,IP,OP,CM,R,SM, and MAA operations. The execution of these operations is unified on the PAcube macro-cell array. Based on this PAcube macro-cell array, we present a novel processor element called the GIPOP processor, which has dedicated functional units to perform the above operations. The architecture and organization of these functional units are such to satisfy the two important criteria mentioned above. The structure of the macro-cell and the unification process has led to a very regular and simpler design of the GIPOP processor. The production cost of the GIPOP processor is drastically reduced as it is designed on high performance mask programmable PAcube arrays. Author (revised)

SYNTHESIS ALGORITHM OF VLSI MULTIPLIERS FOR ASIC **c61**
O. H. Chua and A. G. Eldin *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 13 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

Multipliers are critical sub-blocks in ASIC design, especially for digital signal processing and communications applications. A flexible multiplier synthesis tool is developed which is capable of generating multiplier blocks for word size in the range of 4 to 256 bits. A comparison of existing multiplier algorithms is made in terms of speed, silicon area, and suitability for automated synthesis and verification of its VLSI implementation. The algorithm divides the range of supported word sizes into sub-ranges and provides each sub-range with a specific multiplier architecture for optimal speed and area. The algorithm of the synthesis tool and the multiplier architectures are presented. Circuit implementation and the automated synthesis methodology are discussed. Author (revised)

DESIGN AND IMPLEMENTATION OF GaAs HBT CIRCUITS WITH ACME
Brad L. Hutchings and Tony M. Carter (Utah Univ., Salt Lake City.) *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 10 p Sponsored by DARPA (For primary document see N94-21079 05-33)
Avail: CASI HC A02/MF A06

GaAs HBT circuits offer high performance (5-20 GHz) and radiation hardness (500 Mrad) that is attractive for space applications. ACME is a CAD tool specifically developed for HBT circuits. ACME implements a novel physical schematic-capture design technique where designers simultaneously view the structure and physical organization of a circuit. ACME's design interface is similar to schematic capture; however, unlike conventional schematic capture, designers can directly control the physical placement of both function and interconnect at the schematic level. In addition, ACME provides design-time parasitic extraction, complex wire models, and extensions to Multi-Chip Modules (MCM's). A GaAs HBT gate-array and semi-custom circuits have been developed with ACME; several circuits have been fabricated and found to be fully functional . Author (revised)

EXPERIMENTS ON TECHNOLOGY MAPPING USING DIFFERENT CELL LIBRARIES
Enrico Macii (Politecnico di Torino, Italy.) and Massimo Poncino (Politecnico di Torino, Italy.) *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p (For primary document see N94-21079 05-33)
Avail: CASI HC A02/MF A06

Technology mapping is one of the major steps in the synthesis process of integrated circuits. Efficient algorithms have been proposed in the recent past to optimize the number of cells required to implement a given design, but not enough effort has been spent in studying the relationship between the quality of the circuit produced by the logic synthesis tool and the cell library used to perform the mapping. In this paper we present experiments on technology mapping that show how the design of the cell library can influence the area and the delay of the synthesized circuit. Author

RELIABLE INTERFACE DESIGN FOR COMBINING ASYNCHRONOUS AND SYNCHRONOUS CIRCUITS
Lueli Josephson, Erik L. Brunvand, Ganesh Gopalakrishan, and John F. Hurdle *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

In order to successfully integrate asynchronous and synchronous designs, great care must be taken at the interface between the two types of systems. Synchronizing asynchronous inputs with a free running clock can cause well-known problems with metastability in the synchronization circuits. Stretchable clocks allow a clock cycle to expand dynamically in response to the metastability effects of sampling asynchronous inputs. We use an interface organization where the special circuitry for detecting metastability and for stretching the clock that is delivered to the synchronous part of the system is encapsulated in a Q-flop-based interface. This provides a very convenient method for interfacing mixed systems, as the interface and clock generation circuitry are isolated into one special module, and neither the asynchronous nor the synchronous system need be modified internally to accommodate the interface. This is especially important when standard synchronous components are used as there is no opportunity to modify these parts. We show that this interface module is suitable for most mixed design needs and conclude with an example. Author

Avail: CASI HC A02/MF A06

VLSI electronic circuits are increasingly being used in space-borne applications where high levels of radiation may induce faults, known as single event upsets. In this paper we review the classical methods of designing fault tolerant digital systems, with an emphasis on those methods which are particularly suitable for VLSI-implementation of finite state machines. Four methods are presented and will be compared in terms of

design complexity, circuit size, and estimated circuit delay.

A FIXED/VARIABLE BIT-RATE DATA COMPRESSION ARCHITECTURE **c60**
Gregary C. Zweigle (Advanced Hardware Architectures, Moscow, ID.), Jack Venbrux (New Mexico Univ., Albuquerque.), and Pen-Shu Yeh *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 9 p (For primary document see N94-21079 05-33)
(Grant NAGw-3292)
Avail: CASI HC A02/MF A06

A VLSI architecture for an adaptive data compression encoder capable of sustaining fixed or variable bit-rate output has been developed. There are three modes of operation: lossless with variable bit-rate, lossy with fixed bit-rate and lossy with variable bit-rate. For lossless encoding, the implementation is identical to the USES chip designed for Landsat 7. Obtaining a fixed bit-rate is achieved with a lossy DPCM algorithm using adaptive, nonuniform scalar quantization. In lossy mode, variable bit-rate coding uses the lossless sections of the encoder for post-DPCM entropy coding. The encoder shows excellent compression performance in comparison to other current data compression techniques. No external tables or memory are required for operation. Author

ARITHMETIC IN LARGE GF(2(EXP n))
Kelly Cameron *In its* The Fifth NASA Symposium on VLSI Design 1993 11 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

The decoding of Reed Solomon (BCH) codes usually requires large numbers of calculations using GF(2(exp n)) arithmetic. Though efficient algorithms and corresponding circuits for performing basic Galois field arithmetic are known, many of these techniques either become very slow or else require an inordinate amount of circuitry to implement when the size of the Galois field becomes much larger than GF(2(exp 8)). Consequently, most currently available Reed-Solomon decoders are built using small fields, such as GF(2(exp 8)) or GF(2(exp 10)), even though significant coding efficiencies could often be obtained if larger symbol sizes, such as GF(2(exp 16)) or GF(2(exp 32)), were used. Algorithms for performing the basic arithmetic required to decode Reed-Solomon codes have been developed explicitly for use in these large fields. They are discussed in detail. Author

A COST-EFFECTIVE METHODOLOGY FOR THE DESIGN OF MASSIVELY-PARALLEL VLSI FUNCTIONAL UNITS **c62**
N. Venkateswaran, G. Sriram, and J. Desouza *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 16 p (For primary document see N94-21079 05-33)
Avail: CASI HC A03/MF A06

In this paper we propose a generalized methodology for the design of cost-effective massively-parallel VLSI Functional Units. This methodology is based on a technique of generating and reducing a massive bit-array on the mask-programmable PAcube VLSI array. This methodology unifies (maintains identical data flow and control) the execution of complex arithmetic functions on PAcube arrays. It is highly regular, expandable and uniform with respect to problem-size and wordlength, thereby reducing the communication complexity. The memory-functional unit interface is regular and expandable. Using this technique functional units of dedicated processors can be mask-programmed on the naked PAcube arrays, reducing the turn-around time. The production cost of such dedicated processors can be drastically reduced since the naked PAcube arrays can be mass-produced. Analysis of the the performance of functional units designed by our method yields promising results. Author

BEHAVIORAL MODEL SIMULATION STUDIES OF AN IMAGE COMPRESSOR Thesis **c60**
Navid Madani and Sterling Whitaker *In* New Mexico Univ., The Fifth NASA Symposium on VLSI Design 1993 8 p (For primary document see N94-21079 05-33)
Avail: CASI HC A02/MF A06

The high initial cost of prototype Very Large Scaled Integrated (VLSI) parts requires that sufficient verifications be made to eliminate design errors before actually producing the prototypes. Logic simulation is the means by which the VLSI engineer can ensure that the design will function properly. The computer time required for logic simulation can be reduced through the use of behavioral models. Behavioral models, however, require time to write and verify and they do not always produce a dramatic speed up in logic simulation time. This paper presents a study of behavioral modeling aimed at discovering which circuit types benefit most from the use of behavioral models for logic simulation. Author

Monolithic microwave integrated circuits (MMIC's) are currently being developed for such applications as satellite communications, radar, and phased array systems. The conventional frequency domain approach for testing MMIC's is difficult and costly. A system is provided for nondestructive probing of MMIC's which overcomes the disadvantages of high cost and inconvenience of the prior art. According to the invention, both the electrical signal provided to the device under test and the sampling of that signal are performed using optical switching. In a preferred embodiment, optical pulses for triggering the input electrical signal and for use as sampling pulses are all derived from a single laser pulse via suitable beam splitters and adjustable delays. A set of samples at one value of delay between the input signal and each of the sample points is taken, and then the delays are adjusted for a further set of samples. This is repeated until enough samples are taken to completely reconstruct the signal waveform, and then a Fourier transform algorithm is used on the time domain waveforms to obtain amplitude and phase as a function of frequency. MINIATURE COLOR DISPLAY, PHASE 4 Final Report, 1 Oct. 1992 - 31 May 1993
Henry Franklin May 1993 41 p
(Contract F33615-91-C-0534)
(AD-A272920; AL/CF-SR-1993-0009-Phase-4) Avail: CASI HC A03/MF A01

A 400 x 300-pixel miniature color display with a resolution of 300 pixels/inch, yielding a 1.3 x 1.0-inch active area, has been demonstrated for helmet-mount applications. The display uses active-matrix subtractive-crystal technology. This approach produces high luminance and full color at each pixel without the loss in addressable resolution that is associated with conventional additive-color displays. A stack of three active-matrix twisted-nematic liquid-crystal light valves, sandwiching cyan, magenta, and yellow color polarizers, is used to generate full color. By spectral tuning of the xenon arc-lamp backlight and the color polarizers, a color gamut comparable to that of a shadowmask color CRT is achieved. Four bits of grayscale are provided for each of the three color primaries, yielding a total availability of 4096 colors. The display produces a peak white luminance of 3500 fL and has an inherent (i.e., dark-field) contrast ratio of 50:1. The preceding figures are sufficient to achieve a 2:1 contrast ratio against a 10,000 fL ambient scene, using typical helmet-mounted display optics. The display refresh rate is 68 Hz. DTIC

VLSI DESIGN FOR RELIABILITY-HOT CARRIER EFFECTS Final Report, Jun. 1991 - Jun. 1992
S. Kang, I. Hajj, Y. Leblebici, C. Diaz, and P. Li Apr. 1993 74 p
(Contract F30602-91-C-0053)
(AD-A271586; RL-TR-93-25) Avail: CASI HC A04/MF A01

The accomplishments during the contract period (28 Jun. 1991 to 27 Jun. 1992) on the computer aided analysis of CMOS device and circuit degradation due to hot-carrier effects are described. The task involved four subtasks: (1) simulation of gate oxide degradation during long-term circuit operation; (2) determination of overall circuit performance after hot-electron stress; (3) probabilistic timing approach to hot-carrier-effect estimation; and (4) parametric macromodeling of hot-carrier-induced degradation in MOS VLSI circuits. The first two parts are continued subtasks while the latter two are new subtasks. In order to simulate the reliability of MOS circuits, both the detailed model and the macromodel are used; the detailed model is used for accurate analysis of small circuits and the macromodel is used for very large circuits for computational efficiency. Since the hot-carrier-induced aging of MOS circuits is input-pattern dependent, an important task is to develop a computationally efficient probabilistic timing approach to hot-carrier-effect estimation without resorting to the Monte Carlo simulation. A new probabilistic approach that accounts for cumulative effects of all input waveform combinations in a single run was developed. DTIC

LONG RANGE FAST TOOL SERVO Final Report, 1 Jun. 1992 - 31 May 1993
G. M. Moorefield, II, Thomas A. Dow, Karl J. Falter, and Paul I. Ro 31 May 1993 19 p
(Contract N00014-92-J-4082)
(AD-A271614) Avail: CASI HC A03/MF A01

The PEC's MAC 100 Fast Tool Servo (FTS) System has demonstrated the efficacy of fabricating off-axis parabolic segments on axis by utilizing a fast tool motion to machine non-rotationally symmetric surfaces. The key to this technique was a servo for the tool motion that had a high-bandwidth coupled with a small range of motion. The Keck telescope, with its thirty-six (36) 1-meter diameter segments, would have been an excellent application for this technology. Since this technology was not available at the time of construction, each mirror segment was fabricated to its desired shape by loading it to a specified deformed shape and polishing it to a spherical contour, then removing the bending loads to allow the segment to relax to the desired asymmetric shape. If the segments of this optic had been constructed on axis with an FTS, the fabrication of the most extreme segment would have required only about 200 micrometers of non-rotational symmetry. However, the demand for larger displacement actuators is being driven by new applications with nonrotationally symmetric components in the millimeter range. This report describes the search for a suitable actuator for a long range fast tool servo system that would allow the fabrication of non-rotationally symmetric optical surfaces with a 1 mm range of servo motion. To allow cost-effective machining of these surfaces, the actuator must also possess a 50 Hz bandwidth (minimum) and 25 nanometer resolution. DTIC

CMU VERY FAST RANGE-IMAGING SYSTEM
Shigeyuki Tada, Andrew Gruss, and Takeo Kanade 10 Oct. 1993 40 p
(Grants NSF MIP-89-15969; NSF MIP-90-47590; ARPA Order 7511)
(AD-A272057; CMU-CS-93-179) Avail: CASI HC A03/MF A01

We present a high-speed range-imaging system based on a VLSI computational sensor developed in the CMU Computer Science Department. The VLSI range sensor is a custom chip consisting of an array of cells which combine photo-sensing and computation. Unlike conventional 'step-and-repeat' light-stripe range finders, our sensor gathers range images in parallel as a scene is swept by a continuously moving, plane of light. A prototype range-finding system has been built using a second-generation sensor and is capable of acquiring a 32 x 32 point frame of 3-D measurements in a millisecond - two orders of magnitude faster than currently available range-finding systems. The accuracy and the repeatability of the acquired range data has been measured to be less than 0.2%. In this paper, we discuss the range-finding system and present experimental results that measure its performance. DTIC

MAGNETIC FORCE MICROSCOPY/CURRENT CONTRAST IMAGING: A NEW TECHNIQUE FOR INTERNAL CURRENT PROBING OF IC'S
A. N. Campbell, E. I. Cole, Jr., B. A. Dodd, and R. E. Anderson 1993 12 p Presented at the 4th European Conference on Electron and Optical Beam Testing of Electronic Devices, Zurich, Switzerland, 1-3 Sep. 1993
(Contract DE-AC04-76DP-00789)
(DE93-040754; SAND-93-1881C; CONF-9309130-1) Avail: CASI HC A03/MF A01

This invited paper describes recently reported work on the application of magnetic force microscopy (MFM) to image currents in IC conductors. A computer model for MFM imaging of IC currents and experimental results demonstrating the ability to determine current direction and magnitude with a resolution of approximately 1 mA dc and approximately 1 micro-A ac are presented. The physics of MFM signal generation and applications to current imaging and measurement are described. DOE

DERIVATION OF A MODEL OF THE EXCITER OF A BRUSHLESS SYNCHRONOUS MACHINE
J. M. Vleeshouwers Jun. 1992 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(EUT-92-E-258; ISBN-9-06-144258-3; ETN-94-94765) Avail: Issuing Activity (European Space Agency (ESA))

The modeling of the brushless exciter for a machine used in a wind turbine is addressed. A brushless exciter reduces the susceptability of the machine to atmospheric conditions and therefore the need for maintenance compared to a synchronous machine equipped with brushes and sliprings. Furthermore, no large excitation winding power supply is needed. In large wind turbines which apply a synchronous machine, these advantages will be vital. A brushless exciter is usually constructed as a small synchronous machine with rectifier. According to manufacturers, exciters are designed to function as a current transformer. The method which has been developed in an earlier resarch project to model the synchronous machine with rectifier is concluded to be applicable to model the exciter, provided that the effect of resistances on the commutation may be neglected. This restricts the technique to modeling exciters of machines in the 100 kW range and larger. For smaller exciters the existing modeling approach is not applicable. Measurements of a small exciter (of a 37.5 kVa machine) show that higher harmonics in the exciter significantly contribute to its behavior. Based on experimental data a simple linear first order dynamic model was developed for the small exciter. The model parameters can be deduced from the steady state current gain and a simple dynamic experiment. ESA

A LABORATORY SYSTEM FOR THE INVESTIGATION OF RAIN FADE COMPENSATION TECHNIQUES FOR Ka-BAND SATELLITES Final Report
James S. Svoboda and Brian A. Kachmar (Analex Corp., Brook Park, OH.) Dec. 1993 12 p Proposed for presentation at the 15th International Communications Satellite Systems Conference, San Diego, CA, 28 Feb. - 4 Mar. 1994
(Contracts NAS3-25266; NAS3-25776; RTOP 506-72-1E)
(NASA-CR-191200; E-8186; NAS 1.26:191200; AIAA Paper 94-0917)
Avail: CASI HC A03/MF A01

The design and performance of a rain fade simulation/counteraction system on a laboratory simulated 30/20 GHz, time division multiple access (TDMA) satellite communications testbed is evaluated. Severe rain attenuation of electromagnetic radiation at 30/20 GHz occurs due to the carrier wavelength approaching the water droplet size. Rain in the downlink path lowers the signal power present at the receiver, resulting in a higher number of bit errors induced in the digital ground terminal. The laboratory simulation performed at NASA Lewis Research Center uses a programmable PIN diode attenuator to simulate 20 GHz satellite downlink geographic rain fade profiles. A computer based network control system monitors the downlink power and informs the network of any power threshold violations, which then prompts the network to issue commands that temporarily increase the gain of the satellite based traveling wave tube (TWT) amplifier. After the rain subsides, the network returns the TWT to the normal energy conserving power mode. Bit error rate (BER) data taken at the receiving ground terminal serves as a measure of the severity of rain degradation, and also evaluates the extent to which the network can improve the faded channel. RESULTS FROM LONG CONDUCTION TIME PLASMA OPENING SWITCH EXPERIMENTS AT SANDIA NATIONAL LABORATORIES
M. E. Savage, W. W. Simpson, and M. A. Usher (General Technology Corp., Albuquerque, NM.) 1993 6 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019063; SAND-93-0153C; CONF-930616-32) Avail: CASI HC A02/MF A01

Sandia National Laboratories is conducting research on Plasma Opening Switches (POS) with input current fluxing times of 200-250 nanoseconds. The opening switches that were studied at Sandia employ auxiliary magnetic fields to control the switch plasma. Results are presented from the latest series of experiments on the MITE pulser. Mite will presently deliver 650 kA in 250 ns to a short at the opening switch position. The MITE experiment is unique because it uses a 15 ns long (one-way) transmission line for the storage inductor. This is important for efficiency when the POS is used to transfer energy into an inductive load. The distributed storage inductor also allows pulse-shaping into resistive loads. The plasma injection methods used and the effects of the magnetic fields are discussed. Results from operation of the switch into electron beam loads at voltages from 2 to 3 megavolts are shown. The load voltage risetime 15 to 30 nanoseconds. Important to vacuum opening switch work is the electron flow downstream of the POS. Anode and cathode current measurements downstream of the switch are shown and how switch operation affects electron flow is discussed. DOE

ULTRAFAST GAS SWITCHING EXPERIMENTS
C. A. Frost, T. H. Martin, P. E. Patterson, L. F. Rinehart, G. J. Rohwein, L. D. Roose, J. F. Aurand, and M. T. Buttram 1993 5 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019071; SAND-93-0114C; CONF-930616-28) Avail: CASI HC A01/MF A01

Recent experiments which studied the physics of ultrafast gas breakdown under the extreme overvoltages which occur when a high pressure gas switch is pulse charged to hundreds of kV in 1 ns or less are described. The highly overvolted peaking gaps produce powerful electromagnetic pulses with risetimes less than 100 ps which can be used for ultrawideband radar systems, particle accelerators, laser drivers, bioelectromagnetic studies, electromagnetic effects testing, and for basic studies of gas breakdown physics. Pulses with 50 to 100 ps risetimes to peak levels of 75 to 160 kV at pulse repetition frequencies (PRF) to 1 kHz were produced and accurately measured. A unique gas switch was developed to hold off hundreds of kV with parasitic inductance less than 1 nH. An advanced diagnostic system using Fourier compensation was developed to measure single-shot risetimes below 35 ps. The complete apparatus is described and waveforms are presented. The measured data are compared with a theoretical model which predicts key features including dependence on gas species and pressure. This technology was applied to practical systems driving ultrawideband radiating antennas and bounded wave simulators. A thyristor/pulse transformer based system using a highly overvolted cable switch was developed. This pulser driving a Sandia-designed TEM cell, provides an ultra wideband impulse with less than 200 ps risetime to the test object at a PRF greater than 1 kHz at grater tha n 100 kV/m E field. DOE

LOCALIZATION OF PELLICLE-INDUCED OPEN CONTACTS USING CHARGE-INDUCED VOLTAGE ALTERATION
E. I. Cole, Jr. and J. M. Soden 1993 8 p Presented at the 1993 International Symposium on Testing and Failure Analysis, Los Angeles, CA, 15-19 Nov. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019407; SAND-93-0456C; CONF-931191-1) Avail: CASI HC A02/MF A01

The recently developed Charge-Induced Voltage Alteration (CIVA) technique for localizing open metal conductors was used successfully to identify transistors with electrically open metal-1 contacts to silicon. The transistors were in the I/O port circuitry of a failing microcontroller and were completely covered by a metal-2 power bus. The root cause of the open contacts was a subtle scratch in the pellicle over the contact reticle. The scratch prevented full exposure of the photoresist, resulting in incomplete removal of the interlevel oxide in several contact windows. In addition to this powerful new application of CIVA, a number of failure analysis techniques utilizing both the electrical and physical properties of the failing microcontrollers were employed to identify and confirm the open contacts. These techniques are reviewed and recommendations are given for improved pellicle/reticle inspection. DOE

PROCESS CHARACTERIZATION AND CONTROL OF HAND-SOLDERED PRINTED WIRING ASSEMBLIES
D. L. Cheray and R. G. Mandl Sep. 1993 42 p
(Contract DE-AC04-76DP-00613)
(DE93-041290; KCP-613-5258) Avail: CASI HC A03/MF A01

A designed experiment was conducted to characterize the hand soldering process parameters for manufacturing printed wiring assemblies (PWA's). Component tinning was identified as the most important parameter in hand soldering. After tinning, the soldering iron tip temperature of 700 degrees F and the choice of operators influence solder joint quality more than any other parameters. Cleaning and flux/flux core have little impact on the quality of the solder joint. The need for component cleaning prior to assembly must be evaluated for each component. DOE

N94-21654# Sandia National Labs., Albuquerque, NM.
IMPROVEMENT OF THE STABILITY OF THE PROCESS FOR SYNTHESIZING CHEMICALLY PREPARED VARISTOR POWDER
S. J. Lockwood and E. V. Thomas Aug. 1993 34 p
(Contract DE-AC04-76DP-00789)
(DE94-000345; SAND-92-1986) Avail: CASI HC A03/MF A01

Varistor material is currently supplied by a single commercial source. The chem-prep varistor process was developed as a backup/replacement. With the transfer of the process to the production facility, studies were made to verify that the process is stable in manufacturing. Process variables are the precursors oxalic acid, NaOH, and ZnCl2. Process stability was determined by comparing assay uncertainty region with precipitant/ZnCl2 compositional region meeting electrical and physical property specifications. Assay variability was assessed by conducting a round robin; standard deviations of repeated assays of the same sample was 0.1 wt% by the same labs; 0.1-0.4 wt% among laboratories. A mixture experiment was then conducted to assess the effects of the precipitants/ZnCl2 on breakdown field, nonlinearity coefficient, and bulk density. Results indicate that the chem-prep process can be stable; however the nominal target composition was on the edge of the composition region, and it was moved to the center of the large region with acceptable electrical and physical properties. Tests of unpotted component rods made from the new composition met all specifications. DOE

SIMULATION OF TRAVELING-WAVE OUTPUT STRUCTURES FOR HIGH POWER RF TUBES
K. R. Eppley Apr. 1993 3 p Presented at the International Particle Accelerator Conference, Washington, DC, 17-20 May 1993
(Contract DE-AC03-76SF-00515)
(DE93-041005; SU-SLAC-Pub-6234; CONF-930511-435) Avail: CASI HC A01/MF A01

Travelling wave output structures can in principle provide higher efficiency and lower surface gradients than a single output cavity. We discuss simulations of TW structures designed for X-band klystrons to be used in the SLAC NLC. The PIC Code CONDOR calculated efficiency over 50 percent for one such circuit. When the circuit was built in the SLAC XC7 klystron, the match was so poor that it had to be modified. When tested, the tube produced less than half the efficiency calculated. We subsequently found significant differences between the field distribution calculated by CONDOR versus that from the 3-D code MAFIA. We have now developed a procedure which gives much better agreement between the 2D and 3-D models. We use a (pi)/2 disk-loaded structure, with the waveguide coupling to an output cavity through an iris, rather than directly to the drift tube as in the XC7. The disk radii are tapered to produce an approximately constant gradient. The output coupling is adjusted to match to a uniform structure replicating the cell before the waveguide. The simulations predict 75 MW, 49 percent efficiency, with peak surface fields of 73 MV/m from a 440 kV, 350 amp beam at 11.424 GHz. DOE

THE 1992 4TH NASA SERC SYMPOSIUM ON VLSI DESIGN
Sterling R. Whitaker 1992 422 p Symposium held in Moscow, ID, 29-30 Oct. 1992
(Grant NAGw-3293)
(NASA-CR-194591; NAS 1.26:194591) Avail: CASI HC A18/MF A04

Papers from the fourth annual NASA Symposium on VLSI Design, co-sponsored by the IEEE, are presented. Each year this symposium is organized by the NASA Space Engineering Research Center (SERC) at the University of Idaho and is held in conjunction with a quarterly meeting of the NASA Data System Technology Working Group (DSTWG). One task of the DSTWG is to develop new electronic technologies that will meet next generation electronic data system needs. The symposium provides insights into developments in VLSI and digital systems which can be used to increase data systems performance. The NASA SERC is proud to offer, at its fourth symposium on VLSI design, presentations by an outstanding set of individuals from national laboratories, the electronics industry, and universities. These speakers share insights into next generation advances that will serve as a basis for future VLSI design. For individual titles, see N94-21695 through N94-21735.

SINGLE EVENT PHENOMENA: TESTING AND PREDICTION
James D. Kinnison *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 11 p (For primary document see N94-21694 05-33)
Avail: CASI HC A03/MF A04

Highly integrated microelectronic devices are often used to increase the performance of satellite systems while reducing the system power dissipation, size, and weight. However, these devices are usually more susceptible to radiation than less integrated devices. In particular, the problem of sensitivity to single event upset and latchup is greatly increased as the integration level is increased. Therefore, a method for accurately evaluating the susceptibility of new devices to single event phenomena is critical to qualifying new components for use in space systems. This evaluation includes testing devices for upset or latchup and extrapolating the results of these tests to the orbital environment. Current methods for testing devices for single event effects are reviewed, and methods for upset rate prediction, including a new technique based on Monte Carlo simulation, are presented. A 20 MHz CMOS REORDER BUFFER FOR A SUPERSCALAR MICROPROCESSOR **c60**
John Lenell, Steve Wallace (California Univ., Irvine.), and Nader Bagherzadeh (California Univ., Irvine.) *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 11 p (For primary document see N94-21694 05-33)
Avail: CASI HC A03/MF A04

Superscalar processors can achieve increased performance by issuing instructions out-of-order from the original sequential instruction stream. Implementing an out-of-order instruction issue policy requires a hardware mechanism to prevent incorrectly executed instructions from updating register values. A reorder buffer can be used to allow a superscalar processor to issue instructions out-of-order and maintain program correctness. This paper describes the design and implementation of a 20MHz CMOS reorder buffer for superscalar processors. The reorder buffer is designed to accept and retire two instructions per cycle. A full-custom layout in 1.2 micron has been implemented, measuring 1.1058 mm by 1.3542 mm.

ON THE DECOMPOSITION OF SYNCHRONOUS STATE MECHINES USING SEQUENCE INVARIANT STATE MACHINES
K. Hebbalalu, S. Whitaker, and K. Cameron *In its* The 1992 4th NASA SERC Symposium on VLSI Design 1992 10 p (For primary document see N94-21694 05-33)
Avail: CASI HC A02/MF A04

This paper presents a few techniques for the decomposition of Synchronous State Machines of medium to large sizes into smaller component machines. The methods are based on the nature of the transitions and sequences of states in the machine and on the number and variety of inputs to the machine. The results of the decomposition, and of using the Sequence Invariant State Machine (SISM) Design Technique for generating the component machines, include great ease and quickness in the design and implementation processes. Furthermore, there is increased flexibility in making modifications to the original design leading to negligible re-design time. Author (revised)

A STATISTICAL-BASED SCHEDULING ALGORITHM IN AUTOMATED DATA PATH SYNTHESIS **c61**
Byung Wook Jeon and Chidchanok Lursinsap *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 8 p (For primary document see N94-21694 05-33)
Avail: CASI HC A02/MF A04

In this paper, we propose a new heuristic scheduling algorithm based on the statistical analysis of the cumulative frequency distribution of operations among control steps. It has a tendency of escaping from local minima and therefore reaching a globally optimal solution. The presented algorithm considers the real world constraints such as chained operations, multicycle operations, and pipelined data paths. The result of the experiment shows that it gives optimal solutions, even though it is greedy in nature.

In addition to the widely recognized advantages of full dielectric isolation, e.g., reduced parasitic capacitance, transient radiation hardness, and processing simplicity, fully-depleted silicon-on-sapphire offers reduced floating body effects and improved thermal characteristics when compared to other silicon-on-insulator technologies. The properties of this technology and its potential impact on advanced VLSI circuitry will be discussed.

DESIGN AND TEST OF FIELD PROGRAMMABLE GATE ARRAYS IN SPACE APPLICATIONS **c61**

Priscilla L. McKerracher, Russel P. Cain, Jon C. Barnett, William S. Green, and James D. Kinnison *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 2 p (For primary document see N94-21694 05-33)

Avail: CASI HC A01/MF A04

Field Programmable Gate Arrays (FPGAU's) offer substantial benefits in terms of flexibility and design integration. In addition to qualifying this device for space applications by establishing its reliability and evaluating its sensitivity to radiation, screening the programmed devices with Automatic Test Equipment (ATE) and functional burn-in presents an interesting challenge. This paper presents a review of the design, qualification, and screening cycle employed for FPGA designs in a space program, and demonstrates the need for close interaction between design and test engineers. DEFECT-SENSITIVITY ANALYSIS OF AN SEU IMMUNE CMOS LOGIC FAMILY

Erik H. Ingermann and James F. Frenzel *In its* The 1992 4th NASA SERC Symposium on VLSI Design 1992 10 p (For primary document see N94-21694 05-33)

(Grant NAGw-1406)

Avail: CASI HC A02/MF A04

Fault testing of resistive manufacturing defects is done on a recently developed single event upset immune logic family. Resistive ranges and delay times are compared with those of traditional CMOS logic. Reaction of the logic to these defects is observed for a NOR gate, and an evaluation of its ability to cope with them is determined. Author (revised)

LINKS BETWEEN N-MODULAR REDUNDANCY AND THE THEORY OF ERROR-CORRECTING CODES **c61**

V. Bobin (Hewlett-Packard Co., Santa Clara, CA.), S. Whitaker, and G. Maki *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 11 p (For primary document see N94-21694 05-33)

(Grant NAGw-1406)

Avail: CASI HC A03/MF A04

N-Modular Redundancy (NMR) is one of the best known fault tolerance techniques. Replication of a module to achieve fault tolerance is in some ways analogous to the use of a repetition code where an information symbol is replicated as parity symbols in a codeword. Linear Error-Correcting Codes (ECC) use linear combinations of information symbols as parity symbols which are used to generate syndromes for error patterns. These observations indicate links between the theory of ECC and the use of hardware redundancy for fault tolerance. In this paper, we explore some of these links and show examples of NMR systems where identification of good and failed elements is accomplished in a manner similar to error correction using linear ECC's. REDUCTION OF BLOCKING EFFECTS FOR THE JPEG BASELINE IMAGE COMPRESSION STANDARD **c61**

Gregary C. Zweigle and Roberto H. Bamberger (Washington State Univ., Pullman.) *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 11 p (For primary document see N94-21694 05-33)

(Grant NSF MIPS-91-16683)

Avail: CASI HC A03/MF A04

Transform coding has been chosen for still image compression in the Joint Photographic Experts Group (JPEG) standard. Although transform coding performs superior to many other image compression methods and has fast algorithms for implementation, it is limited by a blocking effect at low bit rates. The blocking effect is inherent in all nonoverlapping transforms. This paper presents a technique for reducing blocking while remaining compatible with the JPEG standard. Simulations show that the system results in subjective performance improvements, sacrificing only a marginal increase in bit rate. Author (revised)

A NOVEL VISUAL HARDWARE BEHAVIORAL LANGUAGE **c61**

Xueqin Li and H. D. Cheng *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 12 p (For primary document see N94-21694 05-33)

Avail: CASI HC A03/MF A04

Most hardware behavioral languages just use texts to describe the

behavior of the desired hardware design. This is inconvenient for VLSI designers who enjoy using the schematic approach. The proposed visual hardware behavioral language has the ability to graphically express design information using visual parallel models (blocks), visual sequential models (processes) and visual data flow graphs (which consist of primitive operational icons, control icons, and Data and Synchro links). Thus, the proposed visual hardware behavioral language can not only specify hardware concurrent and sequential functionality, but can also visually expose parallelism, sequentiality, and disjointness (mutually exclusive operations) for the hardware designers. That would make the hardware designers capture the design ideas easily and explicitly using this visual hardware behavioral language. Author (revised)

HDL TO VERIFICATION LOGIC TRANSLATOR
J. W. Gambles and P. J. Windley *In its* The 1992 4th NASA SERC Symposium on VLSI Design 1992 12 p (For primary document see N94-21694 05-33)
(Grants NAGw-1406; NSF MIP-91-09618)
Avail: CASI HC A03/MF A04

The increasingly higher number of transistors possible in VLSI circuits compounds the difficulty in insuring correct designs. As the number of possible test cases required to exhaustively simulate a circuit design explodes, a better method is required to confirm the absence of design faults. Formal verification methods provide a way to prove, using logic, that a circuit structure correctly implements its specification. Before verification is accepted by VLSI design engineers, the stand alone verification tools that are in use in the research community must be integrated with the CAD tools used by the designers. One problem facing the acceptance of formal verification into circuit design methodology is that the structural circuit descriptions used by the designers are not appropriate for verification work and those required for verification lack some of the features needed for design. We offer a solution to this dilemma: an automatic translation from the designers' HDL models into definitions for the higher-ordered logic (HOL) verification system. The translated definitions become the low level basis of circuit verification which in turn increases the designer's confidence in the correctness of higher level behavioral models. Author (revised)

A SIMPLE MODERN CORRECTNESS CONDITION FOR A SPACE-BASED HIGH-PERFORMANCE MULTIPROCESSOR **c60**
David K. Probst and Hon F. Li *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 10 p (For primary document see N94-21694 05-33)
(Grants NSERC-A3363; NSERC-A0921; NSERC-MEF0040121)
Avail: CASI HC A02/MF A04

A number of U.S. national programs, including space-based detection of ballistic missile launches, envisage putting significant computing power into space. Given sufficient progress in low-power VLSI, multichip-module packaging and liquid-cooling technologies, we will see design of high-performance multiprocessors for individual satellites. In very high speed implementations, performance depends critically on tolerating large latencies in interprocessor communication; without latency tolerance, performance is limited by the vastly differing time scales in processor and data-memory modules, including interconnect times. The modern approach to tolerating remote-communication cost in scalable, shared-memory multiprocessors is to use a multithreaded architecture, and alter the semantics of shared memory slightly, at the price of forcing the programmer either to reason about program correctness in a relaxed consistency model or to agree to program in a constrained style. The literature on multiprocessor correctness conditions has become increasingly complex, and sometimes confusing, which may hinder its practical application. We propose a simple modern correctness condition for a high-performance, shared-memory multiprocessor; the correctness condition is based on a simple interface between the multiprocessor architecture and a high-performance, shared-memory multiprocessor; the correctness condition is based on a simple interface between the multiprocessor architecture and the parallel programming system. INSTRUCTION SET COMMUTIVITY **c61**
P. Windley *In its* The 1992 4th NASA SERC Symposium on VLSI Design 1992 11 p (For primary document see N94-21694 05-33)
(Contract MDA904-91-C-7054)
Avail: CASI HC A03/MF A04

We present a state property called congruence and show how it can be used to demonstrate commutivity of instructions in a modern load-store architecture. Our analysis is particularly important in pipelined microprocessors where instructions are frequently reordered to avoid costly delays in execution caused by hazards. Our work has significant implications to safety and security critical applications since reordering can easily change the meaning and an instruction sequence and current techniques are largely ad hoc. Our work is done in a mechanical theorem prover and results in a set of trustworthy rules for instruction reordering. The mechanization makes it practical to analyze the entire instruction set. DETECTION OF FEED-THROUGH FAULTS IN CMOS STORAGE ELEMENTS
Waleed K. Al-Assadi, Yashwant K. Malaiya, and Anura P. Jayasumana *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 5 p Sponsored in part by SDIO/IST (For primary document see N94-21694 05-33)
Avail: CASI HC A01/MF A04

In testing sequential circuits, internal faults in the storage elements (SE's) are sometimes modeled as stuck-at faults in the combinational circuits surrounding the SE. The detection of some transistor-level faults that cannot be modeled as stuck-at are considered. These feed-through faults cause the cell to become either data-feed-through, which makes the cell combinational, or clock-feed-through, which causes the clock signal or its complement to appear at the output. Under such faults, the cell does not function as a memory element. Here it is shown that such faults may or may not be detected depending on delays involved. Conditions under which race-ahead occurs are identified. Author (revised)

A VLSI IMPLEMENTATION OF DCT USING PASS TRANSISTOR TECHNOLOGY

S. Kamath, Douglas Lynn, and Sterling Whitaker *In its* The 1992 4th NASA SERC Symposium on VLSI Design 1992 12 p (For primary document see N94-21694 05-33)
(Grants NAGw-1406; NSF MIP-91-09618)
Avail: CASI HC A03/MF A04

A VLSI design for performing the Discrete Cosine Transform (DCT) operation on image blocks of size 16 x 16 in a real time fashion operating at 34 MHz (worst case) is presented. The process used was Hewlett-Packard's CMOS26--A 3 metal CMOS process with a minimum feature size of 0.75 micron. The design is based on Multiply-Accumulate (MAC) cells which make use of a modified Booth recoding algorithm for performing multiplication. The design of these cells is straight forward, and the layouts are regular with no complex routing. Two versions of these MAC cells were designed and their layouts completed. Both versions were simulated using SPICE to estimate their performance. One version is slightly faster at the cost of larger silicon area and higher power consumption. An improvement in speed of almost 20 percent is achieved after several iterations of simulation and re-sizing.

LOW ENERGY CMOS FOR SPACE APPLICATIONS
Ramesh Panwar and Leon Alkalaj *In* Idaho Univ., The 1992 4th NASA SERC Symposium on VLSI Design 1992 15 p (For primary document see N94-21694 05-33)
Avail: CASI HC A03/MF A04

The current focus of NASA's space flight programs reflects a new thrust towards smaller, less costly, and more frequent space missions, when compared to missions such as Galileo, Magellan, or Cassini. Recently, the concept of a microspacecraft was proposed. In this concept, a small, compact spacecraft that weighs tens of kilograms performs focused scientific objectives such as imaging. Similarly, a Mars Lander micro-rover project is under study that will allow miniature robots weighing less than seven kilograms to explore the Martian surface. To bring the microspacecraft and microrover ideas to fruition, one will have to leverage compact 3D multi-chip module-based multiprocessors (MCM) technologies. Low energy CMOS will become increasingly important because of the thermodynamic considerations in cooling compact 3D MCM implementations and also from considerations of the power budget for space applications. In this paper, we show how the operating voltage is related to the threshold voltage of the CMOS transistors for accomplishing a task in VLSI with minimal energy. We also derive expressions for the noise margins at the optimal operating point. We then look at a low voltage CMOS (LVCMOS) technology developed at Stanford University which improves the power consumption over conventional CMOS by a couple of orders of magnitude and consider the suitability of the technology for space applications by characterizing its SEU immunity. HIGH POWER, ELECTRON-BEAM INDUCED SWITCHING IN DIAMOND
R. D. Scarpetti, W. W. Hofer, D. R. Kania, K. H. Schoenbach, R. P. Joshi, C. Molina, and R. P. Brinkmann (Old Dominion Univ., Norfolk, VA.) Jul. 1993 6 p Presented at the 9th IEEE Pulsed Power Conference, Albuquerque, NM, 21-23 Jun. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-040535; UCRL-JC-112023; CONF-930616-37) Avail: CASI HC A02

We are developing a high voltage, high average power, electron-beam controlled diamond switch that could significantly impact high power solid-state electronics in industrial and defense applications. An electron-beam controlled thin-film diamond could switch well over 100 kW average power at MHz frequencies, greater than 5 kV, and with high efficiency. This performance is due to the excellent thermal and electronic properties of diamond, the high efficiency achieved with electron beam control, and the demonstrated effectiveness of microchannel cooling. Our electron beam penetration depth measurements agree with our Monte-Carlo calculations. We have not observed electron beam damage in diamond for beam energies up to 150 keV. We describe our experimental and calculational results and research objectives. DOE

OPERATION OF A TEST BED AXIAL-GAP BRUSHLESS DC ROTOR WITH A SUPERCONDUCTING STATOR

J. W. McKeever, C. W. Sohns, S. W. Schwenterly, R. W. Young, Sr., V. W. Campbell, M. H. Hickey, G. W. Ott, and J. M. Bailey 1993 42 p Presented at the International Cryogenic Engineering and Materials Conference, Albuquerque, NM, 12-16 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC05-84OR-21400)

(DE93-019167; CONF-930703-21) Avail: CASI HC A03

A variable-speed axial-gap motor with a stator consisting of four liquid helium cooled superconducting electromagnets (two pole pairs) was built and proof tested up to 608 rpm in November 1990 as a tool for joint industry-laboratory evaluation of coils fabricated from high temperature oxide superconductors. A second rotor was fabricated with improved material, winding configuration, and wire type, and the drive system was modified to eliminate current spiking. The modified motor was characterized to design speed, 188 rad/s (1800 rpm), to acquire a performance baseline for future comparison with that of high temperature superconducting (HIS) wire. As it becomes commercially available, HTS wire will replace the low temperature electromagnet wire in a stator modified to control wire temperatures between 4 K and 77 K. Measurements of the superconducting electromagnetic field and locked rotor torque as functions of cryocurrent and dc current through two phases of the rotor, respectively, provided data to estimate power that could be developed by the rotor. Back emf and parasitic mechanical and electromagnetic drag torques were measured as functions of angular velocity to calculate actual rotor power developed and to quantify losses, which reduce the motor's efficiency. A detailed measurement of motor power at design speed confirmed the developed power equation. When subsequently operated at the 33-A maximum available rotor current, the motor delivered 15.3 kW (20.5 hp) to the load. In a final test, the cryostat was operated at 2500 A, 200 A below its critical current. At rotor design current of 60 A and 2500 A stator current, the extrapolated developed power would be 44.2 kW (59.2 hp) with 94% efficiency. DOE

(DE93-019604; UCRL-JC-112510; CONF-930616-34) Avail: CASI HC A02/MF A01

In this study, we limited our questions to ORNL discussing their models with almost a dozen staff members from four divisions. We collected some low-level data about the models, and we also tried to gain a sense of the philosophy of the modeler and how each model fit into the larger perspective of ORNL's and the scientific community's efforts. Time and budget prevented us from conducting any larger study, but we have no reason to suppose that conclusions about ORNL's models and modelers could not be extended to the larger scientific community. SELF ASSEMBLY: AN APPROACH TO TERASCALE INTEGRATION

S. Singer 1993 15 p Presented at the 11th International Invitational Symposium on the Unification of Analytical, Computational, and Experimental Solution Methodologies, Danvers, MA, 18-20 Aug. 1993

(Contract W-7405-eng-36)

(DE93-040104; LA-UR-93-2957; CONF-9308138-2) Avail: CASI HC A03/MF A01

Surely one of the most remarkable accomplishments of modern times has been the miniaturization of electronic components starting with discrete transistors and leading to Very Large Scale Integrated (VLSI) Circuits which will soon contain almost 100 million components in a few square centimeters. It led to an information processing industry that fuels almost every aspect of industrial societies and that has brought manifold benefits to their citizens. Although continuation of the miniaturization process is likely to produce even greater benefits, many experts are concerned that extrapolation of traditional silicon VLSI techniques will meet with increasingly severe difficulties. Some of these are fundamental in nature, e.g., granularity and fluctuations in semiconductors and interconnects and proximity effects such as tunneling. The first major difficulty to be encountered will be a rising cost of products due to increased complexity and difficulty of manufacturing and assembly. Such difficulties are likely to be seen in about 10 years when minimum component sizes are expected to decrease below 0.15 - 0.2 microns. If alternatives to present VLSI techniques are to be available when needed, work on them must start now. At Los Alamos, we are exploring the feasibility of ultrasmall wires and switches that self-assemble themselves into computing elements and circuits. Their operation is based on the quantum properties of nanometer scale molecular clusters. This paper will describe our efforts in the development of these components and will summarize our work in four areas: (1) the development of conducting molecular wires; (2) conducting nanoparticle wires and switches based on the Coulomb Blockade principle; (3) the development of advanced architectures that benefit from the use of such components and that significantly advance the art of high performance computing; and (4) the development of novel methods for attaining sub-Angstrom 3-D non-destructive imaging. This paper briefly summarizes micromachined actuator and sensor capabilities at the Microelectronics Development Laboratory (MDL) of Sandia National Laboratories. These include efforts utilizing either bulk or surface micromachining with silicon substrates. On going developmental projects utilizing both surface and bulk micromachining along with the MDL's effort to integrate a baseline CMOS process with micromachined elements are presented. The paper is broadly divided into three major headings: Surface Micromachined Projects, Bulk Micromachined Projects, and the CMOS/Micromachining Integration Project. DOE

Through the ages each culture and civilization has expressed its values and world view in the form of monuments derived from its most advanced and valued technologies. From pyramids to cathedrals, skyscrapers and moon rockets, our technology has enabled us to leave our mark on the landscape and in the minds of our people. In the 21st century, the compelling technology will be that of the micro-world, enabling the fabrication of structures with features smaller than the wavelengths of light. Such structures

will allow us to monitor and control electrical, chemical, and optical phenomena in ways never before imagined. As in the past, we will continue to create monuments, but the technological monuments of the 21st century will likely be viewed through a microscope. This report provides a discussion of microtechnology in the 21st century. DOE

Sandia National Laboratories, an 8500+ person, multiprogram research and development facility operated for the US Department of Energy, has over 400 research, development and applications scientists and engineers working on sensor technologies. Sandia's 20 person Microsensors Research and Development Department has invented, developed and fielded sensor systems based on acoustic, fiber optic, and silicon microelectronic technologies. These sensors have been used for diverse applications inducting the monitoring of cleaning chemical concentrations in industrial process effluent streams, detection of explosive gas concentrations in aging industrial equipment, real-time measurements of fluid viscosity in equipment lubricants, and monitoring of contaminant concentration levels in ultrapure process gases. Representative sensor technologies available for technology transfer will be described including bulk acoustic wave resonators, surface acoustic wave devices, fiber optic micromirror sensors, and silicon microelectronic sensors. ESTIMATION OF AR SIGNAL PATTERNS USING COMPETITIVE NEURAL NETWORKS **c32**
Keqin Gao, M. Omair Ahmad, and M. N. S. Swamy *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The estimation of signals which are outputs of several unknown signal generating systems is investigated. The case of signals generated from autoregressive (AR) systems is discussed. A limited number of AR predictors are used to estimate the signals. Each of them is treated as a neuron in a competitive neural network. Competition is performed among the neurons to determine which neuron represents the current signal segment, and the weight vector of the winner is updated by an approximate gradient algorithm. The signal representation achieved with the neural network is in the parameter space of the signal model, while the inputs to the network are observed samples. Two advanced competitive algorithms, namely weighted initial competition and Kohonen's self-organizing map, are used in the current scheme. Simulation results are presented to illustrate the performance for various cases. Author (CISTI)

SIGNAL CLASSIFICATION AND NOISE FILTERING USING ARTIFICIAL NEURAL NETWORKS **c32**
Andrew M. Veronis and Demetri Michalopoulos (California State Univ., Fullerton.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An approach is presented for filtering and classifying communication signals using artificial neural networks. Two separate neural network topologies are used to accompliish the task. A recirculation network is employed to implement noise filtering and a probabilistic network to implement classification. An analysis is provided of the classification of signals in the presence of extensive noise. The communications signals used for data analysis were digitally reproduced amplitude-, frequency-, and phase-shift keying waveforms. The ability of a neural network to detect and identify imperfections characteristic of transmitter faults is also explored. The faults injected into the neural network system seek to simulate data from various stations, such that the neural network's ability to isolate a signal to a particular source is being modeled. Finally, suggestions for further enhancement are suggested. Author (CISTI)

NOISE FILTERING USING MULTILAYER FEEDFORWARD NEURAL NETWORK
Hon-Keung Kwan *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A feedforward neural network for random noise filtering was developed, consisting of an N-input N-output L-layer feedforward structure. The number of neurons at each of its hidden layers can be flexible. The network is trained to recognize the original form of signal contaminated by random noise. After training, the network can be used to filter out a noisy signal. The learning algorithm used by the network is described and preliminary simulation results are presented of a two-layer feedforward network with nine inputs, nine hidden neurons, and nine output neurons. The results indicate that such a network can be used for filtering random noise. However, the effectiveness of the method depends very much on training, which is time-consuming. Author (CISTI)

A 3-D VISION METHOD FOR ESTIMATING WORKSPACE OCCUPANCY OF A POWER-LINE MAINTENANCE ROBOT **c63**
Alain Croteau, Denis Laurendeau, and Jean Lessard (Institut de Recherche de l'Hydro-Quebec, Varennes.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A telerobotic system for power-line maintenance is equipped with a laser range-finder allowing it to perform an estimation of its workspace occupancy. The model used for describing space occupancy is described, along with the three dimensional computer vision method developed for extracting this information. The model consists in building an octree of the scene from several range images taken from various points of view. A calibration is performed using the first image in order to find the initial position of the camera relative to the scene. Successive three dimensional images are used to complete the model information until a satisfactory knowledge of the space occupancy is reached. Author (CISTI)

DIRECTIONAL CODING OF MORPHOLOGICAL PYRAMIDAL REPRESENTATIONS **c61**
Zi-Heng Zhou and Anatasios N. Venetsanopoulos *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Morphological directional decomposition based image coding is a novel coding method for achieving high compression ratio while preserving spatial image features. A previous study is extended to focus on the structure and the analysis of the morphological direction filter bank used for directional feature decomposition. Four basic morphological filters are reviewed, and a multiresolution morphological representation called feature-width morphological pyramid is discussed. This pyramid is used for the extraction of image features at various resolutions. A more sophisticated 8-direction filter bank is introduced to replace the simple 4-direction bank, and its directional characteristics are analyzed. The directional decomposition coding method is then presented along with experimental results. The advantage of the new method is an additional 60 percent bit rate reduction achieved from feature coding. Author (CISTI)

OPTIMAL OBJECT MODELLING FOR AN ACTIVE-VISION SYSTEM **c63**
X. He, B. Benhabib, and K. C. Smith *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new active-vision system is under development in order to develop an efficient three dimensional object recognition method for vision-based robotic assembly. In this system, objects are pre-marked with artificial markers in order to simplify the image analysis process. In this context, objects are represented in the vision model by a small set of their two dimensional perspective projections, referred to as standard-views, where each standard-view is defined by a corresponding marker. The optimal number of markers and their best locations on the objects must be determined a priori so that the objects can be efficiently modeled. A solution to this optimization problem is presented, where for a given set of objects the number of markers is minimized and the distinctiveness of the standard-views which are determined by these markers is maximized. An algorithm based on dynamic programming is developed to reach the solution. Author (CISTI)

HIERARCHICAL SURFACE TRIANGULATION OF RANGE DATA **c61**
Marc Soucy and Denis Laurendeau *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A surface triangulation technique is presented which describes surfaces at different levels of resolution in a range image. A two-dimensional Delaunay triangulation of all points is first computed in the parametric grid of the range view. Then, a sequential optimization process removes, at each iteration, the point that minimizes the local retriangulation approximation error caused by its removal. The process can be stopped at any time to obtain a desired level of approximation error. Practical aspects of the implementation of the hierarchical triangulation algorithm are discussed. The data structures issued to represent a triangulation and control the sequential optimization process are described, and it is shown how these structures can be used to increase the speed of the algorithm. The retriangulation of a region after a point is removed from the triangulation is explained. Author (CISTI)

SEGMENTATION AND FITTING BY RESIDUAL CONSENSUS **c61**
Xin-Ming Yu, T. D. Bui, and A. Krzyzak *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A robust segmentation and surface fitting technique is presented which is very useful for computer vision based on range images. The method randomly samples appropriate image points and fits them into selected primitive types. From K samples, residual consensus is measured to choose a best fitting for a homogeneous surface patch. The residual consensus algorithm is not sensitive to outliers. A convergable histogram method is used to measure and compare residuals on various noise levels. The method segments data points of range images into first and second order primitives, and works very well even in smooth connected curve regions. Author (CISTI)

VLSI ARCHITECTURES FOR THE NEW (T,L) ALGORITHM **c32**
P. A. Bengough and S. J. Simmons *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Trellis coding techniques have seen much use in error correction codes for space and satellite applications. When long sequences of data are encoded, the number of possible paths through the trellis becomes great and a trellis search algorithm must be used to determine the path that best matches the received data sequence. The (T,L) algorithm is a new reduced complexity trellis search algorithm, applicable to data sequence estimation in digital communications, that adapts to changing channel conditions. Its simplicity and inherent parallelism suits it well for very large scale integration (VLSI) implementation. A number of alternative VLSI architectures are presented which can be used to realize this algorithm. While one uses a simple nonsorting structure, two other sorting designs based on parallel insertion and weavesorting algorithms are proposed. The area-time performance of the various architectures is compared. Author (CISTI)

AN IN-PLACE AND IN-ORDER ALGORITHM FOR THE DISCRETE COSINE TRANSFORM **c64**
Zhong-De Wang, G. A. Jullien, and J. J. Soltis *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An in place and in order algorithm for the discrete cosine transform (DCT) is introduced. The algorithm is based on the cosine factor fast cosine transform (CFFCT) algorithm which uses the Hadamard order for the indexing of the input sequence. A method to embed the unscrambling of the Hadamard ordering into the butterfly structure of the CFFCT leads to an in place and in order algorithm for the DCT. An in place and in order algorithm for the inverse DCT (IDCT) can be obtained simply by reversing the signal flowgraph, and the algorithm can be applied to both the DCT and the IDCT. Author (CISTI)

FORMAL HARDWARE VERIFICATION IN MAPLE **c60**
F. Mavaddat *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A model is proposed for the Maple based specification of synchronous hardware, to aid in formal verification of several classes of hardware designs. Maple is an algebraic system for symbolic computation, and is also a programming language primarily used for algebraic computations. Given a Maple model (a program) of a design, the program is executed to derive

the system's symbolic behavior. The Maple model is also used to compare the derived and reference behaviors. The advantages of the Maple verification method are: (1) simplicity of the input language; (2) emphasis on arithmetic domain; and (3) strength of the methodology. The Maple based proof technique is applied to combinational circuits, sequential circuits and counters to illustrate the method. Author (CISTI)

SYSTEM LEVEL MODELLING USING PETRI NETS AND VHDL **c60**

A. C. Woo and L. E. Peppard *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Petri nets offer very large scale integration (VLSI) system designers a powerful modelling paradigm at the highest level of abstraction. Hardware description languages such as VHDL were created to capture designs at all levels of abstraction, but often require more detail than is available at preliminary stages of design. Four criteria for the translation of high level modelling paradigms into VHDL are: (1) the VHDL code must functionally model the behavior of the original system; (2) the resulting code should be efficient, both in execution and in the number of lines of code; (3) the VHDL code should be clear so that the original structure is evident; and (4) the amount of VHDL code should grow linearly with increasing complexity of the original description. To illustrate the process the dining philosophers problem is modeled with a petri net and translated into VHDL. Two aspects of VHDL, the lack of global variables and the lack of a random number generator, significantly increased the inefficiency of the simulation.

FORMAL VERIFICATION OF AN ALU **c60**

G. Birtwistle *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The formal verification of an adder based arithmetic logic unit (ALU) is outlined. The formal verification was undertaken using the HOL proof assistant and took 4 weeks. The proof was conducted from the bottom up and was partitioned as: (1) specifying and verifying the half adder and full adder; (2) specifying and verifying the ripple carry adder; (3) specifying and verifying the modified adder subsystem; (4) specifying and verifying the bank of input filters; and (5) completing the hierarchy by wiring together the modified adder subsystem and the bank of input filters, and proving that it meets specification. The formal verification was faster than that recorded for a similar verification using a more automated first order system, and was far quicker than would be possible using simulation. The proof methodology used the proof assistant itself to increase confidence in specifications by unfolding their definitions (symbolic simulation) and also proving some of their consequences. IMPACT OF PARTITIONING ON PARALLEL DISCRETE EVENT SIMULATION OF LOGIC CIRCUITS

B. Nandy and W. M. Loucks *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The issue of partitioning for parallel discrete event simulation (PDES) of logic circuits is addressed. An analysis is performed to calculate the upperbound of the simulation performance improvement and the available concurrency in the circuit. An efficient iterative improvement algorithm similar to Fidducia-Mattheyse (1982) for effective partitioning of the logic circuit simulation is presented. The algorithm attempts to minimize the communication overhead and uniformly distribute the execution load among the processors. The partitioned circuit has been simulated on a transputer network. It shows that performance of conservative logic simulation can be improved with proper partitioning of circuits over random partition by 10-15 percent. Author (CISTI)

TESTS OF LOGIC SPACES: A NEW STRATEGY FOR CERTIFYING THE ACCURACY OF PROGRAMS [TESTS DES ESPACES LOGIQUES: UNE NOUVELLE STRATEGIE POUR CERTIFIER L'EXACTITUDE DES PROGRAMMES] **c61**

Pierre Veronneau and Pierre-N. Robillard *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new strategy applied to program testing is presented. The strategy certifies the absence of errors in the logic spaces of a program. Every program decomposes into a finite number of logic spaces. The output variables of a logic space aro modeled by vector, polynomial, or multinomial space. A finite number of tests are then required for certifying the absence of calculation errors in the logic space. The absence of errors is defined with respect to the requirements or real specifications of the program. Earlier research has demonstrated that the number of tests is finite for any program encountering this model. This test strategy is applied to payroll software having various types of data such as pointers, matrices, and data in dynamic memory. In addition, the strategy determines the extent and veracity of global predicates always with respect to the program requirements or specifications. The limits and possibilities of this strategy are discussed. Author (CISTI)

MODELING SOFTWARE SYSTEMS FOR DATA FLOW TESTING **c61**

Bo Yang and Hasan Ural (Ottawa Univ., Ontario.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Software modeling is very useful in software analysis and testing. Data flow testing requires selection of execution paths such that each individual, sequence, or group of data flow associations, known as definition-use pairs or du-pairs, captured in a program model are covered to a certain extent. For data flow testing, it is necessary to have a model which is capable of representing both control flow and data flow in a program. The well known def-use graph (DUG) is such a model. It is shown that DUG as well as some other program models are incapable of accurately representing inter-procedural data flow. DUG is then extended to overcome the problem. It is illustrated with a Pascal program that more accurate data flow testing can be achieved if the program is modeled by an extended DUG (EDUG). The EDUG consists of a DUG for each procedure, including the main procedure. The EDUG resolves many issues in modeling inter-procedural data flow and is capable of modeling control flow as well as both intra-procedural and inter-procedural data flow in a subprogram.

THE CONFORMANCE TESTING METHODOLOGY TO CTRON (COMMUNICATION AND CENTRAL TRON) EXTENDED OS **c61**

Yoshiaki Terashima, Hiroshi Matsuyama, Akira Otsuka, and Tsutomu Iwahashi *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A conformance testing methodology of communication softwares is presented. The test objective is to achieve portability not only in protocol service level but also in programming interface level. OSI was chosen as the protocol service level standard, and CTRON (communications and central TRON) was chosen as the programming interface level specification. OSI protocol standards have been studied to keep connectibility between different

implementations. The objective of the testing methodology is to determine whether implementations are conformed to the OSI protocol standards at the points of communication control block (CCB) specification. The methodology accords with OSI conformance testing methodology and framework in an abstract test level, and provides a method to carry out conformance tests in an execute level. Two tools are offered to support the methodology: a customization environment for a specific layer interface and a development environment of test scenario programs. The methodology was applied to PBX software development and its feasibility and efficiency were confirmed. Author (CISTI)

A SHARED BUFFER MEMORY SWITCH WITH MAXIMUM QUEUE AND MINIMUM ALLOCATION **c60**

Xing Chen and Jeremiah F. Hayes *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Buffering is required in any type of packet switch structure in order to avoid packet loss whenever there are multiple input packets arriving for the same output. A shared buffer memory switch architecture is proposed. In this switch, a shared buffer pool and a dedicated buffer pool are properly handled for switching and buffering the packets. Being able to prevent monopolization of shared buffers and to secure a full utilization of all the N output channels, the sharing policy with maximum queue and minimum allocation provides good traffic characteristics especially under unbalanced or bursty traffic. The packet loss rate is examined under both balanced and unbalanced traffic. Author (CISTI)

A ONE-SHOT ACCESS SCHEME FOR A MULTICAST SWITCH

Xing Chen, Jeremiah F. Hayes, and M. K. Mehmet Ali *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The capability of handling multipoint connections is essential for many communication needs. Input port queueing along with a contention resolution algorithm is used to resolve output request conflict. A study of the performance of a one-shot access scheme for a multicast packet switch is presented. The analysis is based on an assumption of random traffic, modeled by a Bernoulli process of packet arrival and Bernoulli trials of copy distribution patterns. Input port queueing along with random-selection policy is used to resolve the output request conflict. The primary performance measurement is the packet delay. A key assumption is that all copies of the same packet must be switched in the same slot. This one-shot discipline is easier to implement than one which disperses transmission over several time slots in small or medium size switching. Simulation results agree almost perfectly with the analysis. Author (CISTI)

SORTING NETWORK FOR THE PARTIAL SELECTION PROBLEM

Jean Belzile, Yvon Savaria, and David Haccoun *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Sorting networks and switching networks are widely used in the communication world. Partial selection networks have applications in areas where a single answer is desired but several paths are explored such as in suboptimal breadth-first tree searching algorithms. A technique is introduced which permits the evaluation of any network in terms of average selection and in terms of the number of elements that are always in the partial selection set. The Banyan network was examined using the method and it was found that the quality of the selection decreases as the size of the input set grows. It was also shown that the sorting networks such as the Banyan are not necessarily the best choices for selection problems. Networks which partially sort two sets and then compare the two sets together can achieve much better selection. These two types of network offer a higher number of guaranteed items than the Banyan network for all considered values of elements. Finally, it was noted that deterministic pre-ordering, if present, can also be used to configure a network. Author (CISTI)

ADDITION OF DECIMAL NUMBERS IN OPTICAL COMPUTING ARCHITECTURE BY WALSH CODED DIGITS **c60**

Asit K. Datta and Sunit K. Sen *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

In the addition of two numbers in optical computing, the need for a 'carry' limits the parallel operation unless some form of coding of numbers is taken into consideration. To overcome this difficulty and also retain the advantageous inherent parallel processing capabilities of optical computing architecture, a method of addition is proposed where the decimal numbers are represented by respective Walsh functions. Addition of Walsh functions is carried out bit-wise in an optical computing architecture where 1 is represented by the presence and 0 by the absence of light. Carry is accommodated by the addition of a carry Walsh wave which is selected according to an index sequence generated after 'shift to the left' operation. Author (CISTI)

IMPROVEMENTS ON THE DESIGN OF OPTIMUM SAW FILTERS WITH THE REMEZ EXCHANGE ALGORITHM

Peter M. Smith and Peter J. Edmonson (Mohawk Coll., Hamilton, Ontario.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Linear phase surface acoustic wave (SAW) devices are usually designed by using methods developed for digital filters. A method for improving the sidelobe suppression of surface acoustic wave filters designed with the Remez exchange algorithm is presented. The Remez exchange algorithm is a numerically intensive optimization method used in the transducer design, and has been shown to be directly applicable to the design of SAW single and multiple passband filters, SAW notch filters, and SAW spectral shaping filters. The algorithm iteratively performs a search for extremal frequencies and computes the corresponding frequency response until an equiripple response is obtained. By choosing the sampling rate in the output transducer such that the ripples in its frequency response misalign with those of the input transducer, improvements in suppression of up to 5 decibels are reported with no degradation in the passband response. Both theoretical and experimental results are presented. Author (CISTI)

One of the problems encountered when implementing algorithms on a fixed point digital signal processor is the need to fully use the available dynamic range, in order to reduce the effects of quantization noise and the accumulation of roundoff error. The problem can be quite severe with speech applications, where the input signal level varies considerably, not only as a function of the speaker but also as a function of his position relative to the handset or microphone. An adaptive digital automatic level control (ALC) algorithm is described. It was designed to adapt the input level of various signals encountered in many applications, particularly toll quality speech. The algorithm enables better use to be made of the dynamic

range available on 16 and 32 bits fixed-point microprocessors. The implementation is done in software using a microprocessor, requiring a high resolution (12 bits and up) analog to digital converter and a few clock cycles from the processor. No delay is introduced in the signal path by the use of the algorithm. It can be added to most microprocessor based speech codes without any hardware modification. Author (CISTI)

SUB-BAND ADAPTIVE NOISE CANCELLING

James G. Ryan and Rafik A. Goubran *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The technique of using sub-band adaptive filters for acoustic noise suppression is examined. Simulation results are presented for experimental systems trained with white noise and colored noise for both decimated and non-decimated sub-band signals. To illustrate the usefulness of the sub-band approach for a real application, the full band and sub-band noise cancellers were applied to car data. Estimates of the input and output power spectra for the different cases are presented. It is shown that the full-band noise canceller is unable to attenuate the noise in the higher frequencies due to the low input signal power in this region. The sub-band decomposition of the input signal can significantly increase the rate as compared to a full-band implementation under certain conditions. This increase in convergence speed is manifested as an increased noise attenuation in those regions of the input spectrum with relatively low amounts of power. In addition, the sub-band processing is seen to eliminate the noise enhancement phenomenon found in acoustic noise cancellers for mobile telephony. Author (CISTI)

The algorithms to calculate and display the path of maximum electromagnetic interference coupling along the perfectly conducting surface of a frustrum cone model of an aircraft nose are developed and revised for the Aircraft Inter-Antenna Propagation with Graphics (AAPG) electromagnetic compatibility analysis code. Analysis of the coupling problem geometry on the frustrum cone model and representative numerical test cases reveal how the revised algorithms are more accurate than their predecessors. These improvements in accuracy and their impact on realistic aircraft electromagnetic compatibility problems are outlined.

CALCULATION OF A DIFFRACTED ELECTRIC FIELD WITH THE AID OF THE METHOD OF EQUIVALENT CURRENTS (MEC) [CALCUL DU CHAMP ELECTRIQUE DIFFRACTE A L'AIDE DE LA METHODE DES COURANTS EQUIVALENTS (MEC)] **c32**

J. Raymond, G. Y. Delisle, J. Bedard (Defence Research Establishment Valcartier, Quebec.), and Y. deVilliers (Defence Research Establishment Valcartier, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The method of equivalent currents (MEC) is a technique for modelling the electric field diffracted by any target, applicable in the high frequency region. The method is based essentially on one or several contour integrals, according to the number of contours comprising the target, of different theoretical electric and magnetic currents generated along the target. These currents are determined starting from a mixture of the diffraction coefficients and the approximation of the field diffracted by a corner, deduced with the aid of the physical theory of diffraction. This method is independent of the directions of incidence and observation. The general concepts on which the MEC rests and some results are presented in the monostatic case during which a cylinder is irradiated by an electromagnetic wave polarized vertically. Coastal radar operating at high frequency (HF) has the potential of monitoring iceberg movement and ship and aircraft traffic over a wide area of ocean. The HF radar cross-section of an aircraft-like scatterer of simple geometry is investigated. At these frequencies, the aircraft size is comparable to the wavelength. The aircraft radar cross-section (RCS) is obtained both by computation and by direct measurement. It is demonstrated that at low frequencies in the HF range, the dorsal fin is the dominant scatterer, but at high HF the fuselage can scatter more strongly than the dorsal fin. Aircraft often carry wire antennas for HF communication, and it is shown that such wires can dramatically alter the RCS of the aircraft near the resonant frequencies of the wire. The RCS of a ship modelled as a parallelepiped with mast is 20-30 decibels larger than that of an aircraft, and is dominated at low HF by the contribution of the mast.

THE CONCEPTUAL DESIGN OF A SHORT-RANGE DISTANCE SENSOR **c74**

S. Jacobi and B. Benhabib *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The conceptual design and analysis of an electro-optical, short-range distance sensor is presented. The sensor is based on the intensity measurement of modulated light signals reflected from the surface of an object whose distance is to be measured. In order to overcome the susceptibility to surface reflectivity of most range-finding sensors, which are based on light-intensity measurements, the proposed sensor uses two in-line detectors. The intensity of a reflected light beam is measured at two different distances from the illuminated surface. The combined information from the two detectors results in distance measurements robust to surface characteristics and surface inclination. The computer simulation of a mathematical model representation indicates acceptable accuracy levels of the computed distance in the range of 0 to 50 mm. This is achieved with surface inclination up to 30 deg with respect to the light beam direction, and with a variable nature of the illuminated surface. Author (CISTI)

SENSOR INTEGRATION AND DATA FUSION FOR OBJECT LOCALIZATION IN ROBOTIC WORKCELLS **c63**

I. Saban, K. C. Smith, and B. Benhabib *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new approach to sensor integration and data fusion for location estimation of an object in a robotic workcell environment is presented. Integration of multiple sensors (both passive and active types) with a data fusion technique can significantly improve the accuracy of an object's estimated location. In the proposed scheme, the sensors are mounted on the robot's end-effector. The passive sensor is a single charge-coupled device (CCD) camera, while the active one is a range meter. By utilizing the mobility of the end-effector, the shape and magnitude of the sensor's hyperspheres can be controlled to achieve the desired performance. The objective is remote recognition of some features by both sensors, and

fusion of the acquired data. An application example of the proposed method, namely object identification and its subsequent grasping by a robotic end-effector is considered. Author (CISTI)

ULTRASONIC SENSOR VISION IN ROBOTICS [VISION PAR SENSEURS ULTRASONIQUES PAR LA ROBOTIQUE] **c63**
Michel Brule and Jean-Luc Dion (Quebec Univ., Trois-Riveres.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p In FRENCH (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A vision system of very low resolution is proposed for the solution of the problem of locating and characterizing the form of an unknown surface, subject to constraints of cost, reliability, and availability of power. The system consists of sensors used in measurement of distances such as ultrasonic sensors. This permits estimation of the form of the visible surface of an object, its orientation and location. After a brief review of the fundamental elements of the sensor data processing method and its algorithms, new modules of analysis and calculation are presented which permit the graphical construction of a two-dimensional image of the shape, orientation, and location of that surface. Results of experimental investigations show that these methods have significant precision. Author (CISTI)

VLSI DESIGN OF A BIT SERIAL PARALLEL PROCESSING 4 EXTENDER CHIP FOR M-PATH CONVOLUTIONAL DECODING **c62**
Martin Chalifoux, Minh Nguyen, Steve Thiffault, Jean Belzile, Yvon Savaria, and David Haccoun *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Forward error correction (FEC) with convolutional codes is an efficient way of improving the reliability of communications systems. A bidirectional M-path decoding algorithm for covolutional codes as well as an architecture for its implementation were proposed at the Ecole Polytechnique de Montreal. An essential building block of this architecture is the extender. The design of a very large scale integration (VLSI) prototype which implements four extenders is described. The layout is largely made in a custom design style, incorporating standard cells for the irregular logic. This mix gives a good balance between area efficiency, design time and layout complexity. The result is a very fast chip with success at a 100 MHz clock rate, with a good core density of 2600 transistors per square milimeter, and is 100 percent testable. Author (CISTI)

MLS SIGNAL-IN-SPACE CATEGORY 3 LANDING HAZARD ANALYSIS **c04**
R. J. Kelly *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The risks associated with a microwave landing system (MLS) signal-in-space and the information displayed to the pilot during approach and landing are large statistical guidance errors, loss of guidance information, and loss of signal integrity. MLS equipment specifications quantify these risks. An analysis is presented to identify the elements in the risk allocation process which formed the basis of MLS Category III specifications. Use of a hazard tree process uncovers the interrelationship between accuracy, continuity of service, and integrity in a way that shows the internal consistency of the MLS system design. The objective of this work is to develop a systems engineering methodology which identifies all the important factors contributing to an accident. As the analysis assumptions are confirmed by operational experience, the risk allocation tree can be updated and refined. Author (CISTI)

APPLICATION OF SCATTERING BY ARRAYS OF CYLINDERS TO MLS SIGNAL PROPAGATION ERROR ESTIMATION **c04**
M. Z. El-Gamal and Do-Duy Hung *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Microwave landing systems (MLS) are collocated with approach light systems (ALS) and with existing instrument landing systems (ILS). Signals radiated from MLS are subject to unwanted reflections and shadowing from the ALS and ILS structures, as well as from the runway hump when it exists. The boundary discrete points method (BDP), originally developed to study the scattering of electromagnetic waves by multiple cylinders of different types, is applied to analyze the MLS signal scattering problem. The ILS localizer and ALS structures are represented by a number of cylinders or a combination of cylinders and spheres. A FORTRAN computer program was used to calculate scattered field. Initial results indicate that BDP is a simple but accurate technique that can be easily utilized to estimate the angle guidance error, path following error, control motion noise, and the power densities of signals from MLS antennas along the approach path of an aircraft and during the rollout for the humped-runway situation. The performance of airborne distance measuring equipment needs to be tested and maintained to ensure that it can operate in its intended mode in a microwave landing system. The capabilities of the test and simulation equipment developed by Republic Electronics are described. The equipment comprises a microprocessor based system that can be used to test the airborne distance measuring equipment interrogation in a shop environment and in both the initial approach and final approach modes of operation. Distance information displayed on a separate display terminal is used to produce path following error and control motion noise calculations. Operator programmable parameters include range, range rate, range acceleration, overflight, radio frequency level, pulse spacing, reply efficiency, and echo. Calculations may also be performed to determine if the equipment is operating within the specified tolerances. Author (CISTI)

MODELING OF COAXIAL-FED MICROSTRIP PATCH ANTENNA BY FINITE DIFFERENCE TIME DOMAIN METHOD **c32**
Chen Wu, Ke-Li Wu, Zhiqiang Bi, and John Litva *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A direct three dimensional finite difference time-domain (FDTD) method is applied to the full-wave analysis of various coaxial-fed microstrip antennas. The model is shown to be an efficient and accurate tool for modeling coaxial-fed structures where, in this case, a transverse electromagnetic mode wave is excited by a source. The input impedance of the coaxial-fed microstrip antenna can be determined from the simulated time-domain wave that is reflected down the coaxial line. Two coaxial-fed microstrip antennas are used as examples, one a single element and the other a two-element stacked patch antenna. Excellent agreement over a wide frequency range is demonstrated in both cases between the measured and the FDTD-derived results. Author (CISTI)

A BROADBAND V-ANTENNA FOR PULSED FIELD MEASUREMENTS: EXPERIMENTAL RESULTS **c32**
Karu P. Esselle and Stanislaw S. Stuchly (Ottawa Univ., Ontario.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A broadband receiving antenna was implemented using a resistively loaded thin-film V-monopole and a 500-ohm oscilloscope probe. The pulse-receiving performance of the antenna was evaluated using a time-domain antenna range. The antenna was also tested in a transverse electromagnetic mode cell, both in time and frequency domains. The antenna was found capable of receiving a 520-ps approximately Gaussian pulse, incident within 45 deg from the boresite direction, with good fidelity. The frequency domain receiving transfer function of the antenna is within -57 + or - 3 dB in the 22 MHz-1.1 GHz frequency range. Author (CISTI)

A solution is offered to the general problem of a waveguide coupled to an arbitrary region through a rectangular aperture of arbitrary dimensions. An equivalence principle is used to reduce the original problem to two canonical problems, one for each side of the aperture. The only coupling is through the aperture, whose characteristics can be expressed by one aperture admittance matrix for each region. Application of the boundary conditions (the continuity of the tangential electric and magnetic fields) results in an integral equation, which can then be solved numerically for determining the equivalent magnetic current, which in turn is related to the tangential component of the electric field in the aperture. A moment method is then used to reduce the integral equation to a matrix equation to compute the current coefficients. The procedure is illustrated by considering the radiation from a waveguide fed aperture. Quantities computed are the transmission coefficient, the equivalent magnetic currents, and the gain pattern. LANGUAGE AS PRIMARY DIMENSION OF DISTRIBUTED AI SYSTEMS ACTIVITY **c63**
B. Chaib-Draa *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Research into the structures of multi-agent systems and the nature of multi-agent interactions is currently increasing, expecially for distributed applications such as robotic systems, air traffic control, and man-machine cooperation. A perspective based on language as action is introduced for distributed artificial intelligence systems. Language is described as a coordinated sequence of acts between participants, leading them to a mutual recognition of their mental states. If interacting plans are considered as mental plans binding agents' mental states (beliefs, desires, intentions, and commitments) to actions, the language/action must then facilitate building such plans. CFAR PROCESSING FOR AIRBORNE PULSE-DOPPLER RADARS **c32**
G. Vrckovnik and D. Faubert *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Constant false alarm rate (CFAR) processors which may be used in airborne pulse-Doppler radar systems are described. Using radar parameters selected for an aircraft flying at Mach 1 and at up to 10 km altitude, a simulation using the ABRSIM airborne radar simulator reveals that a 70 dB clutter peak appears across all of the range gates and many of the Doppler bins, resulting in large CFAR losses with conventional CFAR processors. It is shown that by adaptively blanking the range-Doppler resolution cells which contain clutter, significant performance improvements may be achieved. An adaptive algorithm to determine which resolution cells should be blanked is derived and tested in conjunction with a cell-averaging CFAR processor. The adaptive blanking can be used with other types of CFAR, such as the ordered statistic or greatest-of processors. Author (CISTI)

SPACE-BASED RADAR FOR MOVING TARGET DETECTION **c32**
C. F. Weaver and A. W. Bridgewater (Defence Research Establishment, Ottawa, Ontario.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A space-based radar intended for airborne target detection is studied from a signal processing perspective. Several antenna system concepts are used, including phased arrays and scanned reflectors. Promising signal processing techniques for use with a pulse-Doppler (P-D) approach are reviewed. Constraints and difficulties resulting from the unique nature of spaceborne systems are identified and mitigating techniques are suggested. Most of these problems result from the large satellite velocities which are experienced in low-altitude orbits. High PRF (pulse repetition frequency) and medium PRF waveforms are compared and a high PRF waveform is favored because of the advantages obtained from unambiguous velocity information. Non range eclipsing (NRE) and range eclipsing (RE) waveforms are also compared. The choice of NRE or RE waveform depends on the antenna and power system choice and on the minimization of power system weight. Approaches to clutter cancellation such as displaced phase center antennas (DPCA) and monopulse anomalous nulling are discussed. Generic

DPCA is compared with standard P-D processing and found to be better for the altitudes of interest in the phased array approach. Author (CISTI)

A DIGITAL DEMODULATION SCHEME FOR USE IN A HIGH DYNAMIC RANGE RADAR SYSTEM **c32**

Glen Rempel and George Haslam *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Digital demodulation is a technique whereby the positive frequency component of a narrowband signal is translated to baseband by digital means. With this technique, the dynamic range of some radar systems can be greatly increased. A digital demodulation scheme suitable for an airborne radar system is described, and some of the major design issues in its implementation are analyzed. The demodulation process first involves downconversion of the signal to an intermediate frequency (IF), filtering the resulting signal to reduce its frequency sidelobes, mixing the filtered signal to a second IF, digitizing the second IF signal, and filtering the digital signal with a lowpass finite impulse response filter. An expression for the optimal filter is derived, maximizing the ratio of the positive frequency clutter power to the negative frequency clutter plus noise power. Simulated input and output spectra are shown. The simulation results were validated by a simple experiment. Author (CISTI)

MARINE BOUNDARY LAYER MODEL EVALUATION BY USING A HEIGHT GAIN MEASUREMENT TECHNIQUE IN THE INTERFERENCE REGION **c48**

Denis Dion *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Air refractivity is known to produce major effects on electromagnetic propagation in the radio and millimetric bands for paths above large water surfaces. Most of the time, a tropospheric duct is formed within which the energy is trapped. Fading zones may be found at certain elevations and the radiation pattern in the interference region is distorted. The most frequent type of duct is caused by the rapid exponential decrease of the moisture in the marine boundary layer (MBL) at the water surface. Reliable models of the MBL are required to study propagation effects on radar and communication systems. An approach is proposed for evaluating MBL models by comparing model predictions of the variation of the interference null elevation with respect to the refractivity conditions. Two models are considered: a model developed in San Diego called NOSCMBL and the recently issued WKDMBL model. In field tests using X-band radiation, the analysis of height gain and bulk meteorological measurements made over Lake Ontario showed better performances for WKDMBL; an average prediction error of 1.5 m was obtained for an observed null elevation course of about 15 m. THE LOCAL MEASUREMENT AND GLOBAL INTERPRETATION OF 3D MOTION FIELD GENERATED BY SEVERAL MOVING OBJECTS FROM RANGE IMAGE SEQUENCES **c43**

P. Y. Zhu, A. Krzyzak, and T. Kasvand *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new approach is presented for the measurement and interpretation of three dimensional motion field generated by several moving objects from range image sequences. The approach includes six main modules: median filter, local measurement of three dimensional motion field, regularization of the three dimensional motion field, segmentation based on common motion, and determination of motion parameters for each moving part. Results of experiments tested on real and synthetic data with noise are given. Author (CISTI)

SEGMENTING THE OPTICAL FLOW DUE TO THE MOTION OF SEVERAL RIGID OBJECTS **c63**

Rita El-Nmeir and Guy Mailloux (Ecole Polytechnique, Montreal, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Since real objects or observers move in three dimensional space, an important part of research in computer vision has been devoted to motion analysis. Motion information can generally be made computer accessible by serial digitization of each frame of a video recording of the scene to be analyzed. The interframe two dimensional velocity field, or optical flow, can then be computed provided there are enough contours in the images and that the interframe motion is not too fast. A method is presented for computing and segmenting the optical flow due to the motion of several moving rigid objects. Under orthographic projection, the components of the optical flow of a planar surface are describable by linear equations of three parameters each. This constraint is used both to compute the optical flow and to segment it using the generalized Hough transform. This method can be adapted for perspective projection. Author (CISTI)

ELLIPTICAL-SHAPE PARAMETER ESTIMATION FROM A SET OF NORMAL LINES **c61**

I. Tchoukanov, R. Safaee-Rad, B. Benhabib, and K. C. Smith *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new method is proposed for elliptical shape parameter estimation, which does not require detection of the shape's boundary. The values of the parameters of an elliptical shape are estimated based on a set of normal lines to its boundary, computed by an edge detector. The essence of this approach is the use of the relationship between a set of normal lines to an ellipse and the Hough transform of its evolute. The evolute of an elliptical shape is an astroid represented by a shifted sinusoid in the Hough space. It is shown that the values of the elliptical shape parameters could be estimated by utilizing a certain geometrical property of ellipses (for center coordinates) and by analyzing the data in the Hough (parameter) space (for orientation angle, major and minor radii). SCALE-SPACE FILTERING AND THRESHOLD HIERARCHY FOR IMAGE SEGMENTATION **c61**

Neng-Quan Wang, Xue-Dong Yang, and L. R. Symes *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

One common approach to image segmentation is to select thresholds by using local minimum points of the gray level histogram of the image. The histogram for an image is generally not smooth. Also, the use of the minimum values of the histogram as the thresholds is affected by the noise in the original image. The process of the threshold selection can be improved by the smoothing of the histogram. In an extension of Witkin's work on scale-space filtering, scale-space filtering is employed to smooth the original histogram of an image. Furthermore, a new, reliable and accurate method (threshold hierarchy) is presented for image segmentation. The interval tree is designed to display a concise and visible structure of the threshold hierarchy. Experimental results of segmented images with different threshold hierarchies are presented. NEW ALGORITHM FOR THE DETECTION OF THE ORIENTATION OF A PLANAR LAMBERTIAN SURFACE IN 3D **c61**

Przemyslaw Pochec *In* Engineering Inst. of Canada, Canadian Conference

on Electrical and Computer Engineering, Volumes 1 and 2 1991 2 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new image processing algorithm for the detection of the orientation of a planar surface is proposed. The algorithm relies on the ambient light array (ALA) representation of visual information, which is based on recording both the direction and intensity of light rays originating from points on objects in the scene. The algorithm is based on modelling the ALA imaging of a planar surface as a circular (Moebius) transformation - unit inversion. This class of linear-fractional transformations can describe the mapping of a plane to a sphere. In ALA domain, with a point light source close to the observer, the image of a Lambertian plane is a sphere. For the detection of orientation of a planar surface, the intensities of light reflected from only three points on the observed surface are needed. Author (CISTI)

SILICON MICROMACHINED THRESHOLD ACCELEROMETERS **c35**
Y. Loke, G. H. McKinnon, and M. J. Brett *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A threshold accelerometer, also known as a g-switch, was developed for sensing very high acceleration levels. The design follows the concept of a cantilever beam as the sensing element with a metal line running along its length. Under applied acceleration, the beam deflects upwards across a small gap and makes contact with a second electrode, thus closing a switch. The structural material chosen for the beam was silicon dioxide, due to its flexibility and ease in fabrication. The theory of the electrostatic and inertial forces are analyzed and a threshold acceleration level is derived. It is shown that this level is very sensitive to beam length. Fabrication steps are described, including chemical vapor deposition, chemical etching, and fabrication and assembly of the top glass plate. Electrostatic testing that involved voltages representative of threshold acceleration levels of 400 to 100,000 gravities was performed on over 150 beams. Under static centrifuge testing involving over 100 beams, threshold acceleration levels from 400 to 20,000 gravities were measured. Most of the experimental results are within the predicted tolerance limits set by the processing parameters. Author (CISTI)

CHARGE INTEGRATING OPTICAL POSITION SENSOR **c35**
S. Balasubramanian, J. W. Haslett, and F. N. Trofimenkoff *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A modification to a recently described high-resolution optical position sensor increased its optical sensitivity by several orders of magnitude. The modification is based on charge transfer principles and was implemented in a 3-micrometer CMOS technology. One of the major applications of this device is to use it as the sensor in a telescope position control system for star tracking. The device can determine the precise position of the centroid of a diffuse light source focused on its surface, with integration times of a few milliseconds. Author (CISTI)

VLSI DESIGN OF A PARALLEL VIDEO OUTPUT INTERFACE
Eric Boisvert, Abdelhakim Khali, David Lachartre, Mario Larouche, Mohamed Nekili, Abdelmajid Bennani, and Yvon Savaria *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The design and integration of a very large scale integration (VLSI) video output interface (VOI) chip which allows building a scaleable speed VOI capable of extracting images in real time from a parallel machine of an adequate size is presented. The parallel VOI interfaces a massively parallel computer with a packet switched general purpose communication network and a wide range of video displays. Multiple copies of the VOI chip can be used to increase the rate at which results can be extracted from the parallel computer. It is thus possible to extract video images in real time with minimum impact on the performance of the parallel system. The architecture is highly flexible since it can be adapted to various image sizes, formats, number of ports, and throughputs. A VLSI chip based on the proposed architecture was designed and will be integrated in the near future. Extensive functional simulation will have to be carried out to validate the design. MLS POINTING ANGLE ERROR SOURCES AND EFFECTS **c04**
David Babineau, Mike McAloney, and Maurice Meyer *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Angle guidance for aircraft is one of the important functions performed by a microwave landing system. Identification of error sources is required by manufacturers of such systems in order to manage equipment error budgets. An analysis is presented of error sources internal to the angle guidance ground equipment which affect the angle accuracy measured at the aircraft. A straightforward approach for estimating the end effect for some of the error sources is given. The antenna components of the phased arrays typically used in microwave landing systems are divided into three types for the analysis: power divider, phase shifter, and waveguide. Error effects are divided into two categories: amplitude errors and phase errors. Other error sources discussed are those resulting from beam steering and from waveguide/frame parameters. The approach presented is a tool for reasonability checking and for initial design trade studies.

Ada is a programming language mandated for all developmental software by the US DOD, and the Canadian Department of National Defense is also moving in this direction. To respond to these requirements, the Paramax Ada Centre of Excellence was established. Specific defense programs currently targeted include the New Shipborne Aircraft Program, the New Search Helicopter Program, and the US Navy CP 901A Anti-Submarine Warfare Program for the P-3 aircraft. The Ada Centre is supporting the establishment and upgrading of the Ada Development Centre, which contains the necessary MIL-STD-2167A software development process. The underlying architecture is a heterogeneous local area network utilizing unshielded twisted-pair ethernet technology. Hardware includes a VAX 6310 computer and a Sun server supporting Sun, DEC, and Unisys workstations. The software tool of choice is Requirements Entry Allocation and Decomposition Support (READS), which was integrated with the CASE tool from IDE. The Centre also presents Ada training courses and has a technology transfer capability. Author (CISTI)

FORMAL METHODS IN THE DESIGN OF CRITICAL SOFTWARE SYSTEMS **c61**

J. Burns and J. Spruce Riordon (AEPOS Technologies Corp., Hull, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Software used in critical systems such as nuclear power station control, fly-by-wire aircraft, and data encryption should rigorously adhere to system specification. The technology of formal methods (FM) is an essential part of producing security and safety systems to the highest levels of assurance. A current deficiency in FM development is the lack of fully effective tools. In their absence, a pragmatic approach should be adopted and formal techniques applied judiciously. The OBJ/MALPAS methodology has proven to be a practical and effective route to code. FM techniques can be acquired by advanced software engineers without an excessive learning curve. An example is presented of FM techniques applied to a network security example. The OBJ specification equations are translated to an abstract version of the MALPAS intermediate language, and the output is successively refined. For each step in the refinement process it is necessary to show that the refined code meets the specifications of its predecessor. Implementation code is produced manually following the last stage of refinement, and is automatically translated back into the intermediate language and checked for compliance against the OBJ specification.

AN OVERVIEW OF SYNTHETIC APERTURE RADAR SIGNAL PROCESSING TECHNIQUES **c32**

M. R. Vant *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 7 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The principles of synthetic aperture radar and its significance in a military and remote sensing context are reviewed. The signal processing operations required to convert the signal data into an image are described. These operations must accomplish two things: correction of the range migration, both walk and curvature; and compression or focusing of the cross-range portion of the signal. These operations include time-domain deramping, matched filtering, range-Doppler fast convolution, step transform processing, spotlight mode processing, and motion compensation. Processing problems specific to synthetic aperture radar signal processing are summarized and an example of synthetic aperture radar imagery is presented. Author (CISTI)

ADAPTIVE SYNTHESIS OF A RAY DIAGRAM FOR AN ANTENNA ARRAY [SYNTHESE ADAPTIVE D'UN DIAGRAMME DE RAYONNEMENT D'UNE ANTENNE RESEAU] **c32**

D. Grenier *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An algorithm is proposed which is capable of evaluating the optimal weighting of each of the elements of an antenna array. The algorithm has the objective of obtaining a radiation diagram predefined by samples marking the level of several principal lobes, all the while trying to increase the depth of the hollows between these lobes. The proposed algorithm uses the sum of the optimal weighting vectors which maximize the signal to interference ratio in the directions of the main lobes. The algorithm assumes that the signal emitted from each element of the network consists of the following: a useful signal whose azimuth and amplitude correspond to the angle and level of the lobe; a large number of interfering signals originating from many directions; and thermal noise. From several examples it is seen that the obtained solution does not always respect the starting data; nevertheless, the solution corresponds to the optimal solution in the least squares sense. TARGET ANGULAR MOTION AND ITS EFFECTS ON SIMULATED SSAR SHIP IMAGES **c32**

A. Damini and G. E. Haslam *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Synthetic aperture radar (SAR) is an airborne radar mapping technique for generating high resolution images. Spotlight SAR is a mode of SAR in which the radar antenna is trained on the target area of interest. The dependence of the cross-range resolution achievable in spotlight SAR, both on the coherent integration time and the relative angular rotation rate between the radar and the target is described. The orientation of the image as a function of the relative angular motions is also examined. The type of motions experienced by an ocean-going vessel are expected to reduce the quality of a spotlight SAR image. Computer simulations of the radar returns from a spotlighted ocean-going vessel, and the processing of these returns to generate a spotlight SAR image of the ship, support this hypothesis. A fairly high sea state produces an image which is generally a vertical profile view through the target, while lower sea states produce a generally horizontal plan view of the target. Author (CISTI)

EFFECT OF ERRORS ON THE PHASE CENTRE AND POINTING ANGLE OF PHASED ARRAY ANTENNAS **c32**

H. Moheb, A. Helaly (Cairo Univ., Egypt.), A. Sebak, and L. Shafai *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A mathematical model is developed to determine the antenna phase center and its uniqueness. The model is then used to investigate the phase center location for selected small phased array antennas and to determine its movement due to the beam scanning and various design or operational errors. It is shown that for an ideal antenna (the error-free case), the phase center coincides with its geometrical center. However, any deviation from the ideal conditions, due to design, fabrication or operational errors, due to the phase shifter quantization, or due to the scan angle algorithm, causes its non-uniqueness and movement from the antenna's geometrical center. A NEURAL NETWORK FOR MULTIRESOLUTION EDGE DETECTION **c63**

Richard Lepage and Denis Poussart *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A goal of computer vision is the construction of scene descriptions based on information extracted from one or more two-dimensional images. Edge detection makes explicit important information about the two-dimensional image but is scale dependent: edges are visible only over a range of scales. One needs multiple scale analysis of the input image in order to have a complete description of the edges. A compact pyramidal architecture is proposed for image representation at multiple spatial scales. A simple processing element (PE) is allocated at each pixel location at each level of the pyramid. A dense network of weighted links between each PE and PE's underneath is programmed to generate the levels of the pyramid. Lateral weighted links within a level compute edge localization and intensity gradient. Feedback between successive levels is used to reinforce and refine the position of true edges. Author (CISTI)

IMPROVEMENT IN INVARIANT PATTERN RECOGNITION WITH NEURAL NETWORKS AND FOURIER-MELLIN FILTERS **c63**
Claude Lejeune and Yun-Long Sheng *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Fourier-Mellin filters are used to generate shift, rotation, and scale invariant pattern descriptors. The size of these descriptors is quite small compared to the original object that generated them. It has the added advantage of invariance that the original object has not. Their small size permits very fast training with a neural network. This approach is used with a training set of three aircraft. Once learning has taken place, the network is presented with a testing set consisting of those three aircraft and rotated versions of them. The network is able to learn and recognize the original objects as well as the rotated versions. Author (CISTI)

A MODIFIED MOMENT INVARIANTS TECHNIQUE FOR CLASSIFICATION OF NOISY OBJECTS **c61**
Halet Arezki, H. T. Huynh, and G. A. Lampropoulos *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

With moment invariant methods for object classification, features are extracted by computing second and third order moments of the image, and combining them in a vector of seven numbers which is invariant under general linear transformation. These methods can be applied to the classification of binary or textured images, but result in features that are sensitive to noise. An improvement is proposed in which the magnitude of every one of the seven moments is used for normalization, with its power being equal to the order of the moments. These new moments are more steady in a noisy environment and give excellent results for classification of noisy images, as is demonstrated for the case of two types of images, human faces and military aircraft. A NEURAL M-ARY TREE METHOD FOR DATA COMPRESSION
Zhi-Cheng Wang and J. Hanson *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new version of a multilayer neural network, the self-learning neural model, is presented. This neural model can be used as adaptive nonparametric neural net clusters, which can be trained by unlabelled data. An M-ary decision tree structured vector code with the building blocks of this type of neural network is developed for data compression. The M-ary tree codes are systems of loosely coupled hybrid neural networks. They combine the traditional decision tree technique, artificial neural network technique, and hierarchical process in aspects of structure, training, and coding, resulting in new properties and good performance. The feedforward model learns coding without supervision and codes input in a parallel and sequential way. The model is smaller than the normal neural networks used for coding. Author (CISTI)

CREIR: A MULTIACCESS PROTOCOL FOR ON-BOARD PROCESSING SATELLITE SYSTEMS **c60**
Le-Ngoc Tho and Yu-Dong Yao (Spar Aerospace Ltd., Sainte-Anne-de-Bellevue, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Random access and reservation access protocols are studied for satellite communication systems with on-board processing. Explicit then implicit reservation, a protocol to accommodate long message transmissions and to reduce end-user buffer size effects, is introduced and its performance is compared with explicit reservation and implicit reservation performance. The combination of random access and explicit then implicit reservation access results in a new protocol called Combined Random/Explicit then Implicit Reservation (CREIR). The implementation of CREIR in an on-board satellite system is also discussed with reference to the handling of collision detection and data packet slot assignment. Author (CISTI)

TIMING RECOVERY IN THE CHANNEL PROCESSOR OF A DIGITAL GROUP DEMODULATOR
Norman Secord *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

In future generations of satellites, digital group demodulators will be used to regenerate frequency division multiple access (FDMA) / quadrature phase shift keying (QPSK) signals on board the satellite and convert them to a time division multiplexed stream for the return link. The group demodulator consists of a digital trans-multiplexer which separates out the individual FDMA/QPSK signals and a bank of per-channel processors which perform timing and carrier recovery for each channel. Timing recovery is examined within the channel processor of the group demodulator. The timing is adjusted using a finite impulse response filter that acts as an adaptive delay and also decimates the sample sequence to obtain a baud rate sequence from which decisions on the symbols can be made. The design of this adaptive rate control filter is discussed with emphasis on the influence of the tap length and filter response function in acquisition and tracking performance. Author (CISTI)

THE INFLUENCE OF LOWPASS FILTERING AND THE EFFECTS OF FADING ON THE GROUP DEMODULATION OF QPSK SIGNALS **c32**
Norman Secord, Shunkichi Isobe (Ministry of Posts and Telecommunications, Tokyo, Japan.), and Chun Loo *In* Engineering Inst. of Canada, Canadian

Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The influence of the lowpass filter at the front end of a digital group demodulator on the number of usable satellite communication channels is discussed. A Monte Carlo simulation study was undertaken using a raised cosine filter as the lowpass filter response. The group demodulator was designed to accommodate 16 channels of quadrature phase shift keying data with a channel spacing equal to twice the symbol rate. In particular, it is shown that the proper design of this lowpass filter can provide several additional channels. The effects of fading and shadowing on the performance of a signal that is group demodulated are also discussed. The results indicate that the inter-channel interference that is present due to the close channel spacing of the signals combines with the fading to produce a severely distorted signal. This indicates that new receiver structures and the introduction of coding will be required to combat the fading, shadowing, and inter-channel interference for land mobile communications with on-board processing or group demodulation. TDMA SATELLITE COMMUNICATION SYSTEMS FOR ISDN SERVICES **c32**
Katsuhiko Kawazoe, Masahiro Morikura, Shuji Kubota, Kiyoshi Enomoto, and Shuzo Kato *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A time division multiple access (TDMA) satellite communication system is proposed, suitable for integrated satellite and terrestrial services covering both basic interface and primary interface services. To provide these services economically and efficiently, the proposed system employs demand assignment technology for each data burst and a transmitting and receiving transponder (carrier) hopping TDMA scheme. Moreover, to realize cost-effective transmission and subscriber lines and increase reliability of TDMA terminals, major functions of TDMA terminals have been implemented in various types of integrated circuits. The developed TDMA system which provides basic and primary subscriber transmission lines will be in commercial use from mid-1991. Author (CISTI)

A CONSIDERATION OF THE INTEGRATION OF TERRESTRIAL AND SATELLITE MOBILE SYSTEMS **c32**
Masato Mori, Yasuki Nishi, and Hiraku Mishima *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Terrestrial communication systems can handle heavy traffic concentrated in a narrow urban area, but are uneconomic to handle light traffic distributed over a wide area. In satellite systems, communications are available wherever the satellite can be seen. However, such systems have channel capacity limitations which makes them unsuitable for intra-urban communications. The characteristics of each system can be effectively integrated to achieve an economical mobile communications system. A satellite mobile communications system is proposed which is network integrated into a terrestrial cellular system. The network is composed of a transit layer and a local switching layer, with several points of interface. The relationship between the optimum areas of coverage for the satellite system and the terrestrial system is discussed. The system will use the S band as the service link frequency for the multi-beam satellite system communicating with compact mobile terminals. Author (CISTI)

CODING OF COLOR QUANTIZED IMAGES **c61**
Andre Zaccarin and Bede Liu (Princeton Univ., NJ.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Color images are usually compressed in a luminance chrominance coordinate space. Since the compression is done independently for each coordinate, the pixels of the decoded image can take any value in the full color space. If such a technique is applied to an image using a limited palette, the decoded image has to be quantized before it can be displayed with a limited palette. An approach for the compression of color images with limited palette is presented that does not require color quantization of the decoded image. The proposed technique restricts the pixels of the decoded image to take values only in the original palette. Thus, the decoded image can be readily displayed without having to be quantized. For comparable quality and bit rates, the proposed technique significantly reduces the decoder computational complexity. Author (CISTI)

HIERARCHICAL MULTIRATE VECTOR QUANTIZATION FOR IMAGE CODING **c61**
P. Yu and A. N. Venetsanopoulos *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The hierarchical multirate vector quantization (HMVQ) is an improved form of vector quantization for digital image coding. The HMVQ uses block segmentation and a structure tree to divide an original image into several layers and sub-layers according to their grey scale contrast within blocks of a certain size. Variant bit rates are used for block coding of different layers with the same codebook. The codebook consists of several sub-codebooks which are generated separately from their respective layers. The HMVQ technique can provide high quality image reproduction with very low bit rates. The processing time for codebook generation is greatly shortened by using layer by layer optimization and a proper subsampling in low detail regions. The technique also demonstrates a flexibility in accurate reproduction in different detail regions. The accuracy for the recovery of different areas in an image can be adjusted by changing the thresholds, the number of layers, or the sizes of the relative codebooks.

USING STREAM INTERLEAVING TO ELIMINATE THE NEED FOR INTERLOCKS IN DEEPLY PIPELINED PROCESSORS **c62**
Daniel C. McCrackin *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 6 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The performance of a practical multistream mechanism for achieving high utilization of deeply pipelined processors was investigated. The delay enforced multistreaming (DEMUS) mechanism circumvents both control hazards and data hazards in processors with an arbitrary number of pipeline stages. A novel dynamic stream interleaving technique is used to fill gaps in execution required for the correct operation of one stream with useful work for another stream. The control mechanism offers: potentially complete pipeline utilization, reduced performance loss due to data hazards and control hazards, no hardware interlocks, and no-overhead context switching for a hardware limited to a small number of streams. Sufficient delay is introduced after the dispatch of each instruction on each stream so that successive instructions cannot interfere with each other. The simulated performance of three simple stream dispatch mechanisms is presented.

Thin-film fabrication of superconductors is one of the most important fields in the development of advanced superconducting electronic and microwave devices. The processing details and properties are provided for Pb-doped BiSrCaCuO high temperature superconducting thin films. The fabrication processes included preparation of (Pb)BiSrCaCu oxide target in 2:2:2:2:3 cation ratio, deposition of amorphous films using single-target radio frequency magnetron sputtering, and annealing of the as-deposited films for oxygen-vacancy control. The substrates used for the film growth were (100)-oriented single-crystal MgO. The fabricated films, 1 micrometer thick, were a mixture of (001)-oriented 2212- and 2223- superconducting phases. The temperature dependent resistance of the thin films showed very sharp transition in the vicinity of 105 K. The current carrying capability of these films was established to be 3000 amperes per square centimeter at 77 K. Effects of the substrate materials, deposition geometries, and annealing conditions are described. Author (CISTI)

CHARACTERIZATION AND MODELLING OF EXTREMELY HIGH FREQUENCY ENCLOSURES [CARACTERISATION ET MODELISATION DES BOITIERS HYPERFREQUENCES]
M. Gaudreault and M. Cuhaci *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The development of monolithic microwave integrated circuits has prompted the need to develop specific types of enclosures for these circuits. The choice of enclosure depends on the intended frequency of operation since the performance of enclosures is affected by parasitic effects related to their construction and physical characteristics. These effects are caused by transitions, the cavity volume, the effect of the cover, and the electromagnetic coupling between the metallic walls and the encapsulated circuit. Two types of transitions are studied in detail through tests on enclosures made by Technical Components Inc. and by the French company SOREP. Results of time domain measurements are presented showing effects of electromagnetic coupling, covers, and cavity resonance. Many of the effects depend on the enclosure dimensions and all the effects studied contribute to a degradation in performance. The transitions between interior and exterior are the greatest causes of this degradation and their equivalent circuit models have the topology of a low pass filter. Author (CISTI)

MANUAL DESIGN TECHNIQUE FOR BROADBAND PASSIVE THIN-FILM ATTENUATORS USING THE SMITH CHART
H. Do Ky, M. Cuhaci, and A. Ittipiboon *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A manual design procedure for broadband passive thin film attenuators is described, in which the Smith chart is used to calculate attenuator dimensions. The procedure transforms a known terminating impedance to a real value, over a complex characteristic impedance transmission line. The proposed analysis of this transformation eliminates the need for using a complex numerical technique to solve for the input impedance of a resistive transmission line. Good agreement is found between the results from this manual procedure and those from running simulations using Mathematica. The design technique is verified with measured results of fabricated samples of these attenuators up to 26.5 GHz. Author (CISTI)

IMPROVEMENT OF THE PERFORMANCE OF IMPATT OSCILLATORS THROUGH APPROPRIATE MODIFICATION OF RESONANT-CAP ACTIVITY
Subal Kar and S. K. Roy *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A modified resonant-cap IMPATT oscillator has been developed at X band (8-12 GHz) by incorporating appropriately sized circumferential slots on the disc of the resonant-cap structure. The microwave power output of the optimally modified cap oscillator is almost doubled and the bandwidth of electronic tuning improved nearly four-fold compared to the optimized normal circular resonant-cap oscillator. A simple semi-quantitative understanding of these experimental results is outlined. The modified cap cavity has two effective values for the radius of the cap, with an operating frequency corresponding to the average of the two resultant resonant frequencies. This concept appears to be an attractive means of designing powerful solid-state sources of microwave energy with wide, electronically tunable bandwidth which may be useful for communication and radar systems. A SIMPLIFIED METHOD FOR S-PARAMETER CALCULATIONS OF METAL SEPTUM WAVEGUIDE FILTERS
Kerry Zhenglian Cai, Danian Li (Beijing Normal Univ., China.), and Jens Bornemann *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A combined field theoretical and measurement oriented model is presented for the performance evaluation and design of waveguide E-plane filters with all-metal inserts. The analysis is based on both the variational method and general measurement techniques of scattering networks. Compared with previously published algorithms, this procedure is easy to program, uses less computer memory, and offers a better convergence behavior. The calculated scattering parameters include the interaction effects between the fundamental and higher-order modes at the waveguide to metal septum discontinuity. The method is verified by comparing computed data with measured results of three Ka-band filter prototypes. Due to the accurate predictions of the model, good agreement is obtained.

ON THE DISCOVERY OF APPROXIMATE ARITHMETIC RELATIONS BY BACKPROPAGATION NETWORKS **c63**
N. R. S. Simons and H. C. Card *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

In this paper a backpropagation network is used to discover simple arithmetic relations. The first problem examined is that of determining an approximate value or range for the resistance of a wire given its length, cross-sectional area, and resistivity. The operation is performed in a discrete manner in that input and output values are lumped into low, medium, and high bins. In another problem the simpler operation of multiplication is examined to investigate some of the details regarding generalization and memorization, and to evolve improved multiplication rules. The multiplication problem is also re-examined using graded analog data rather than lumped data, and comparison with alternative approaches is made. In conclusion it is shown that an artificial neural network is capable of fitting a solution surface to a data set that is mathematically related. Although the relationships examined are simple examples, many of the conclusions are applicable to more complex arithmetic problems. Author (CISTI)

LOGIC ORIENTED NEURAL NETWORKS **c63**
Robert V. Pelletier, Witold Pedrycz, Robert D. McLeod, and David C. Blight *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Logic networks are a special class of neural network that yield knowledge about the trained system more readily than conventional neural networks.

A new class of logic-based topologies based on mechanisms of fuzzy sets are studied. A detailed description of the proposed logical structure and learning scheme is presented. A number of experiments were performed to illustrate the practical operation of the logic networks. These experiments included: comparing the different methods described using a multi-valued version of the two-input XOR problem; determining the effects of modifying the learning rate and momentum on the convergence speed of the networks; and increasing the size of the network to a three-input XOR function with n=3 and m=4 for the logic networks. Methods other than the Lukasiewicz conjunction must be used for networks larger than two inputs, due to its discontinuous learning derivatives. Author (CISTI)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Neural network optimization techniques are applied to solve the maximum flow problem which is a traffic flow allocation problem with many applications in computer communication networks. Previous attempts to solve the network flow problem for the general multicommodity case have ended up with a linear programming formulation, in which the solution technique, based on the simplex algorithm, suffers from excessive storage and running time requirements especially for large networks. In order to solve the resulting linear programming problem in real time, using a neural network approach, an extended version of the Chau and Lin linear programming network is suggested. The computational power of the extended model is demonstrated through computer simulations. Author (CISTI)

The discrete Fourier transform (DFT) is a valuable tool in signal processing being required in a wide variety of applications. For real-time tasks, fast calculation of the DFT is required. A practical implementation is presented of a modified Hopfield neural net for the computation of an N point DFT. The implementation is based on different configurations of operational transconductance amplifiers, biased in the active region. The use of the actively biased solution is limited to N less than or equal to 256 due to current power dissipation constraints. A drawback of the actively biased solution is its sensitivity to process fluctutations. An implementation in the sub-threshold region will likely find use when power dissipation is a major concern. The convergence time of the circuit is very fast compared to other reported implementations. Ideally, the computation time could decrease as the order of the transformation increases. An advantage of this method of DFT calculation over other processor-based implementations is its relative simplicity of architecture, despite its lack of modularity. Author (CISTI)

An experimental computing system has been installed in a Convair 580 aircraft at the National Research Center (Canada) Flight Research Laboratory. The system is used in a number of research projects in the fields of geophysics, oceanography, and meteorology. The characteristics and performance of this system are described, with a focus on its application in geophysical exploration. In its first configuration, a single centralized minicomputer was used. In this approach, all sensors, conversion equipment, and input-output devices were interfaced directly to the computer. Problems with interrupts, complex input/output structure, and development bottlenecks led to the decision to use front-end processors to perform low-level device handling and data acquisition functions. The resulting distributed computing system retained the main computer and a number of 16-bit microprocessors were added as front-end and auxiliary processors. Current work is aimed at upgrading the various components of the system. A local area network is also being considered to improve data communication in the system. Author (CISTI)

INTERFERENCE REDUCTION USING NEURAL NETWORKS **c63**

H. M. Hafez and G. K. Chan (Department of Communications, Ottawa, Ontario.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The feasibility of using neural networks in detecting binary data in the presence of inter-symbol interference and a strong co-channel interference is investigated. A generic model that combines co-channel and adjacent channel interference is explained and used as a basis for a numerical example demonstrating the strength of the neural network approach. A neural network processor views the data selection as a pattern classification problem. A back propagation algorithm is used to train the network off-line without additive noise. The trained network captures the statistics of the signal plus interference, establishes its own decision boundaries, and stores all the information in the values of the connecting weights. In the example considered, a three-layer neural network detector was trained and then tested in the recall phase for SIR (signal to interference ratios) of 3, 5, and 7 dB. In each test the signal to noise ratio was increased in 3-dB steps until no error could be detected. The bit error rate for the neural network detector at SIR of 7 dB or more was very close to that of binary phase shift keying in an ideal channel. Author (CISTI)

VISIBILITY CONSIDERATIONS IN FREQUENCY SHARING WITH LOW EARTH ORBIT SATELLITES **c32**

John W. Chang *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Recent proposals in data-relay satellite systems indicate the use of multiple low earth orbit (LEO) satellites. These systems usually consist of many small satellites, each of which stays above the horizon for around 15 minutes in each 100-minute orbit. Allocation of frequency bands to this service sharing with existing services, with communication links between fixed points, will require additional considerations. In addition to interference assessment between the shared systems, parameters relating to probability of time exposure should be considered in the evaluation for sharing feasibility. The model used to estimate these parameters in sharing analyses is described. Author (CISTI)

The maintenance of a communications satellite in a geosynchronous orbit requires the combustion of an on-board fuel. It can be of interest, in order to prolong the life of a satellite already in orbit or even to allow

lightening of a satellite at launch, to save onboard fuel by letting the satellite drift in a slightly inclined orbit. The mechanisms which govern the inclination of the orbit are reviewed, followed by the equations which describe the movement of the satellites and the service zones irradiated by their antennas. Once these parameters are defined, their impact on the management of the spectrum and of the orbit is evaluated through an analysis of the possibility of interference with other satellite radio communication systems or even systems in stationary service sharing the same frequency bands. THROUGHPUT AND BLOCKING IN CIRCUIT-SWITCHED INTERCONNECTION NETWORKS
Han-Hua Ma and M. Comeau *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Interconnection networks are applied in communications networks and high performance parallel computers. Contention is the central problem making performance analysis difficult, as it introduces statistical dependencies among the elements of the system. A Markov model is employed to determine throughput and blocking in circuit-switched interconnection networks. Internally nonblocking switches are considered and may be asymmetrically loaded. The model represents blocking at the ports as a relation to the circuits of the switch and yields a product form for the equilibrium distribution of the switch. The computational aspects of the model are greatly simplified for switches of a regular topology, resulting in simple recursions (over the dimensions of the switch) for throughput and blocking. Results are presented for symmetrically loaded networks. Author (CISTI)

THROUGHPUT, BLOCKING, AND INTERFERENCE IN PACKET RADIO NETWORKS **c32**
Han-Hua Ma and Marc Comeau *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A model is described, extended, and applied to determine throughput, blocking, and interference in packet radio networks. Transmission interactions are systematically categorized for a class of channel access protocols yielding a product form Markov chain for the dynamics of the system. Nonpersistant CSMA, BTMA, and directional CSMA (D-CSMA) are modelled within the framework. In addition, two non-realizable protocols, collision-free multiple access (CFMA) and total capacity allocation protocol (TCAP), are introduced as capacity measures for networks with omnidirectional and directional transmission capabilities, respectively. A comparative study of CSMA, BTMA, and D-CSMA is conducted for various networks, using CFMA and TCAP to determine relative capacity utilization. Author (CISTI)

THE SCHUR BERLEKAMP-MASSEY ALGORITHM IS PARALLELIZABLE **c61**
Gordon Chan and Christopher Zarowski *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The Berlekamp Massey algorithm (BMA) is known for its applications in the decoding of error control codes, such as BCH codes. Unfortunately, the BMA does not run efficiently on a parallel computer. The Schur form of the BMA has been derived in order that the algorithm can run efficiently on a linearly connected parallel processor array. Interprocessor communication on the array is strictly local. Using the Schur BMA on a code capable of correcting N/2 errors requires an array of N processors and takes O(N) time to compute the error locator polynomial. The algorithm is superior in the sense that it is regular. That is, if the number of errors the code can correct increases, then more processors may be added to the array. Author (CISTI)

A novel interprocessor network is presented that can be gradually implemented and integrates several modern multiprocessor architectures. The network is particularly suitable for coarse-grain multiprocessor systems. It is also attractive in that many well known architectures requiring different resources from the present network system can be integrated with minimal bus or memory contention. Hardware and software interprocessor synchronization, interrupts, and DMA transfers can be supported. The interconnection system can in its full configuration support a number of processors in a fully interconnected network permitting parallel data exchanges without contention and minimum communication skew. The basic theory behind the approach is presented and examples of integration of parallel processing structures based on the network are given. The implementation and fabrication of the communications hardware are discussed. Author (CISTI)

SPECIFICATION AND FORMAL VERIFICATION OF THE SAFETY CRITERION IN THE ALTERNATING BIT PROTOCOL **c82**
Sylvain Martel, Ian W. Hunter, and Serge Lafontaine *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The alternating bit protocol is one of many protocols designed to transmit data reliably from a sender to a receiver over an unreliable channel. The Milner version of the alternating bit protocol is specified in HOL (the Cambridge higher order logic proof assistant) and checked for the desirable properties of a safe protocol (the order in which messages are given to the sender is the order in which they reach the receiver) and that the protocol is live (all messages given to the sender reach the receiver or the protocol aborts). A description is presented of the alternating bit protocol, expressing the protocol in HOL, and the proof structure. Author (CISTI)

MODELING AND ANALYSIS OF SECURE COMMUNICATION PROTOCOLS USING PETRI NET FORMALISM **c61**
Benjamin B. Nieh and Stafford E. Tavares *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The use of cryptographic techniques is essential for secure network communications. The security of such communication systems depends not only on the strength of the cryptographic algorithms employed, but also on the correctness and security of protocols based on these algorithms. A petri net based modelling and analysis methodology for secure communication protocol studies is presented. Ordinary petri nets, colored petri nets, and a modified petri net model are used to represent protocol entities as a hierarchical set of descriptions and to develop a corresponding intruder model. A security analysis is carried out of the Burns-Mitchell (B-M) protocol and security flaws are discussed. It is concluded that petri nets, a formalism with strong modelling power and theoretical foundation, are a useful tool in the study of security systems, and will play a role in the analysis and development of secure communications protocols. NON-LINEAR ANALYSIS OF THE ELECTRICAL PROPERTIES OF THE ACTIVE CIRCUITS OF HIGH-FREQUENCY OSCILLATORS [ANALYSE NON-LINEAIRE DES ELEMENTS ACTIFS DE L'OSCILLATEUR H.F. ACCORDE ELECTRIQUEMENT]

Salih Aidel, Andrei Szymczak, and Abdellatif Said (Constantine Univ., Algeria.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The parameters of active circuits incorporating high frequency wide-band semiconductors depend strongly on the amplitude of the high frequency signal supplied to it, and circuit analysis must take this fact into account. A new method for analyzing elementary microwave oscillator circuits is proposed, with the objective of predicting the output power of the high-frequency generator. The method is based on an examination of the retreat function of the visible reflectance at the level of the active gate as a function of the power supplied to the circuit of the oscillator in question. An example of an active circuit based on the HP3508238 transistor and a control circuit with the 2H703 varactor are used for illustration. The results obtained have contributed to the optimization of the structure of the oscillator. Author (CISTI)

AlGaAs LASER DIODE FM SPECTRUM: PHASED ARRAY ANTENNA APPLICATION **c32**

Martin Chamberland and Michel Tetu *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Preliminary results are presented on the use of an AlGaAs laser diode to generate microwave signals suitable for application with phased array antennas. The relative intensity noise (RIN) was measured under various operating conditions to give an indication of the frequency response limitation of the laser diode. The frequency response to intensity modulation was also measured directly at microwave frequencies. Finally, the FM spectrum was observed using a heterodyne technique and compared with an empirical model. The spectrum of intensity fluctuations shows a peak near the relaxation oscillation frequency. This is a good indication of the cutoff frequency for direct current modulation of the laser diode. The behavior of the modulated laser diode is well characterized by the simultaneous intensity and frequency modulation taking into account a phase difference between the two. Author (CISTI)

NUMERICAL METHOD FOR COMPUTING THE ELECTRIC FIELD PRODUCED BY A MICROWAVE BEAM IN A STRATIFIED MEDIUM [METHODE POUR L'ETUDE DU CHAMP ELECTRIQUE PRODUIT PAR UN FAISCEAU HYPERFREQUENCE DANS UN MILIEU STRATIFIE] **c32**

Jean Montreuil *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 2 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Microwaves are often used in applications where they interact with stratified media, such as in high-frequency heating, microwave radiometry, and the study of soils and ice. To evaluate the electric fields in the strata, it is necessary to model the radiation from the antenna. A numerical method has been developed for evaluation of the electric field radiated by an antenna into a stratified medium. The radiation is modeled by a beam having a finite rather than infinite width. For several applications, this model is more appropriate and provides more accurate results than the ones based on a beam of infinite width. Author (CISTI)

PERFORMANCE OF A SIMPLE CIRCULAR POLARIZATION SELECTIVE SURFACE **c32**

J. E. Roy, G. A. Morin (Defence Research Establishment, Ottawa, Ontario.), and L. Shafai *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A parametric analysis is presented of a simple circular polarization selective surface (CPSS) performed with the Numerical Electromagnetic Code NEC-2. The application envisaged is a Cassegrain reflector antenna in which the hyperboloidal subreflector is replaced by a flat CPSS in order to minimize the aperture blockage and thereby reduce the sidelobe level of the antenna. As the incidence angle varies from point to point on the subreflector surface, the effect of the incidence angle on the performance of the CPSS becomes of paramount importance. The operation of the unit cell and of an octagonal array made of 37 identical cells (operating frequency 1 GHz) is shown for variations in incidence angle, frequency, and cell size. Author (CISTI)

MHMIC: TECHNOLOGY FOR THE INTEGRATION OF MICROWAVE SUB-ASSEMBLIES [MHMIC: TECHNOLOGIE D'INTEGRATION DES SOUS-ENSEMBLES HYPERFREQUENCES]

R. Douville, M. Cuhaci, and S. Meszaros *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new technology for producing miniaturized microwave circuits is described. This technology is called miniature hybrid microwave integrated circuits (MHMIC) and is a technology which is intermediate between microwave integrated circuits (MIC) and monolithic microwave integrated circuits (MMIC). All the passive elements are produced during the different stages of fabrication, similar to MMIC's. The active devices are added at the end by assembly, using MIC techniques. The main difference between the MHMIC and MIC technologies is the utilization of metallized holes, air bridges, and dielectric layers in MHMIC. The advantages of integrating the passive elements are a significant reduction in assembly cost and in the number of elements to assemble. MHMIC technology gives the designer the choice of active device and allows the miniaturization of circuits while lowering the number of added components. In general, a thin-film technology is used in the fabrication of the various MHMIC elements. The choice of the substrate is generally determined by the final application. One of the first examples of the application of MHMIC is the development of balanced amplifier modules for 8-18 GHz. Some aerospace applications are also under development. Author (CISTI)

A SOFTWARE ENVIRONMENT FOR THE EXPLOITATION OF THE MAR IMAGE SENSOR **c61**

F. Parent, M. Tremblay, D. Laurendeau, and D. Poussart *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The MAR (Multi-port Array Receptor) system combines optical sensing and integrated focal-plane processing capabilities. Its central element is a full custom, very large scale integrated circuit (VLSI) photosensor array with hexagonal tessellation and complex peripheral selection logic which provides parallel analog readout of a group of pixels over prescribed areas. The camera controller uses the information as feedback to perform edge tracking or area scanning. The principal characteristics of the MAR sensor and its controller are reviewed. The software environment is then described, followed by the results of tests performed on digital images.

A PYRAMID NEURAL NETWORK ARCHITECTURE FOR STEREO FUSION **c63**

Shengrui Wang, Simon Gagne (Laval Univ., Quebec.), and Denis Poussart

(Laval Univ., Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A model for reconstruction of three dimensional representation from two dimensional images is proposed. The model is composed of three functional components. A pyramidal neural architecture is elaborated for multiscale edge detection. Important characteristics of the architecture include the introduction of an adaptive mechanism in a competitive neural network and an explicit modeling of multiscale processing. Also proposed is a neural network architecture for edge matching, whose design takes into account psychophysical contraints such as uniqueness and disparity gradient limit. The model is completed by a diffusive filling-in algorithm that can be used to estimate global disparity information by combining shading information (intensity gradient) and known disparities at edge points. Experimental results are provided to illustrate the performance of the model. Author (CISTI)

TWO-DIMENSIONAL PERCEPTION BASED ON A LASER RANGEFINDER [PERCEPTION BIDIMENTIONNELLE A BASE D'UN TELEMETRE LASER] **c36**
G. Allegre and H. Clergeot *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A simple solution for obtaining a three dimensional vision system has been to add a plane sweep deviation system to a precision laser rangefinder. This system has allowed working with noncooperative targets at 12 m distance and at 50 kHz frequency with a precision often better than a millimeter. Coaxial send and receive optical beams enable deviation to be readily accomplished. A compromise is found between rapidity and precision for a given optical power received. Analysis of the causes of variation in signal level explained the observed dynamics, and procedures are suggested to limit these phenomena. Two other critical problems are related to the coupling between paths and to the phase derivatives of the measuring chain. A system of plane deviation offering a vision angle of +/- 30 deg and a maximum frequency of a dozen Hertz was developed using a galvanometric mirror. Dynamic testing of the profiling capability of the system was also conducted. For mobile robotics applications, it is proposed to simplify the system by determining a horizontal profile in two dimensions. This would be sufficient for many purposes and although one dimension would be lost, a significant improvement in response time is expected. Author (CISTI)

BUFFER ALLOCATION IN AN ATM SWITCH WITH OUTPUT BUFFER AND SPEED CONSTRAINTS **c32**
Anil K. Gupta and N. D. Georganas *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A synchronous nonblocking N times N switch for asynchronous transfer mode (ATM) networks or high speed packet switching networks transporting fixed length packets called cells is considered. Such a switch with output queuing achieves the optimal performance, however it requires the switch fabric to work at the speed of N. In practice the switch may operate L times faster than the input/output trunk. It is assumed that queues at each output port have a limited buffer space and whenever an output queue is full, the back-pressure is applied and the packets are retained at the head of the input queues. The upper bound on the packet loss probability at the input queues in such a switch are computed. To achieve a given packet loss rate, the switch with L equals 2 requires almost the same amount of input and output buffers as with L equals 4 up to 70 percent input load, but as the load increases beyond 70 percent the switch with L equals 4 would require more output buffers and less input buffers in comparison with a switch operating at L equals 2. The performance of a switch with L equals 3 is very similar to that for L equals 4 and is not considered. Author (CISTI)

COMPARISON OF THEORETICAL AND SIMULATED PERFORMANCE RESULTS FOR SLOPPY-SLOTTED ALOHA SIGNALING **c32**
Stewart N. Crozier *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Sloppy-slotted Aloha refers to a form of random access signaling which allows slotted packets, with random timing errors, to spill over into adjacent slots. For the North American mobile satellite (MSAT) system, the two-way propagation delay variation is on the order of 40 milliseconds. The higher the signaling rate, or the shorter the packet length, the wider the timing error distribution, measured in packet lengths. With 192 transmission bits per packet, a 40 millisecond timing error corresponds to 2 packet lengths at 9600 bits per second. Approximate theoretical and simulated performance results are presented and compared for a mixed Gaussian discrete timing error distribution model. This model allows a fraction of the users to have corrected timing. It is found that the theoretical approximations are generally quite accurate. Where differences are observed, the theoretical approximations are always found to be pessimistic. The conclusion is that the theoretical approximations can be used with confidence as a conservative measure of performance. Author (CISTI)

NEURAL NETWORKS FOR OPTIMUM ROUTING IN PACKET-SWITCHED COMMUNICATIONS NETWORKS **c32**
Faouzi Kamoun and M. Mehmet Ali *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A neural network solution is applied to the optimum routing problem in packet-switched communication networks, where the goal is to minimize the network-wide average time delay. Under appropriate assumptions it is shown that the optimum routing algorithm relies heavily on shortest path computations that have to be carried out in real time. For this purpose an efficient neural network shortest path algorithm, based on the Hopfield model, is proposed, which is an improved version of the previously suggested neural algorithms. The proposed model enables the routing algorithm to be implemented in real time and also to be adaptive to changes in link cost and network topology. Author (CISTI)

ACCELERATION OF BACKPROPAGATION LEARNING USING A PARALLEL DSP MACHINE **c62**
Glenn K. Rosendahl, Robert D. McLeod, and Howard C. Card *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The backpropagation learning algorithm is of central importance to the field of artificial neural networks. Both analog and digital implementations are progressing, with digital being the most prevalent so far. However, digital implementations suffer from size limitions and long learning times imposed by inadequate computing resources restricting them to problems of primarily academic interest. By implementing the backpropagation algorithm on a parallel processor specifically designed for this task, the solution to larger problems associated with pattern recognition can be achieved. Speech processing, artificial vision systems, and robotic control problems are examples of tasks of practical interest. The overall parallel processor architecture is described, along with an initial implementation of the sigmoid transfer function on a 56000 digital signal processor. Comparisons are made to other high performance very large scale integration systems. Author (CISTI)

IMAGE CONVOLUTION USING THE MYRIAS SPS-2 PARALLEL COMPUTER **c62**

Kalpagam Krishnan, Werner B. Joerg, and Brian Minchau *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The implementation of an image convolution algorithm on the Myrias SPS-2 parallel computer (multiple instruction/multiple data type) is discussed. The architecture of the target system identifies an obvious preference for one of several parallelization schemes of interest. Two conceptually different schemes, namely instruction parallelism and image domain partitioning (a particular form of data parallelism) are considered. Performance studies show an efficiency of 91 percent with 16 processors in the case of instruction parallelism, with nearly linear speedup characteristics. The communication difficulties and the associated overheads are illustrated using the domain partitioning approach. It is observed that image convolution exhibits a processing structure compatible with instruction parallelism resulting in significant performance improvements on the SPS-2 and similar machines.

PARALLELIZING A MAXIMUM ENTROPY IMAGE DECONVOLUTION ALGORITHM **c62**
Werner B. Joerg and Kalpagam Krishnan *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An image deconvolution algorithm based on the maximum entropy method (MEM) was implemented on the Myrias SPS-2 parallel computer, and its performance was studied. The application context of the deconvolution algorithm is the restoration of an unknown object from a known degraded input. The MEM algorithm is a nonlinear constrained optimization problem, solved iteratively using a relaxation scheme. For an image of size 256 by 256, the algorithm shows an efficiency of 78 percent for an optimum number of eight processors when implemented on the SPS-2. The implementation approach and the performance characteristics are discussed including the use of instruction parallelism and domain partitioning.

FILE TRANSFER PERFORMANCE IN LAN INTERCONNECTION THROUGH A SATELLITE CHANNEL **c32**
Xiao-Xiong Yao and Oliver W. W. Yang *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The performance of transferring files from workstations in one local area network (LAN) to workstations in another LAN was studied. Satellite channels and associated gateway stations are used to interconnect these LAN's at different geographical locations. The file transfer performance was simulated using the QNAP2 simulation language. System performance according to delay and throughput criteria were evaluated against system parameters such as file sizes, window sizes, and the number of workstation pairs involved in transmission. Two traffic bottlenecks are identified: one due to the transmission control protocol/internet protocol flow control through its window size and the number of receive buffers; and one due to the queueing in the gateway of the system.

RECOGNIZING HESITATION PHENOMENA IN CONTINUOUS, SPONTANEOUS SPEECH **c32**
Douglas OShaughnessy *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Spontaneous speech differs from read speech in speaking rate and hesitation. In natural, spontaneous speech, people often start talking and then think along the way; at times, this causes the speech to have hesitation pauses (both filled and unfilled) and restarts. Results are reported on all types of pauses in a widely-used speech database, for both hesitation pauses and semi-intentional pauses. A distinction is made between grammatical pauses (at major syntactic boundaries) and ungrammatical ones. Different types of unfilled pauses cannot be reliably separated based on silence duration, although grammatical pauses tend to be longer. In the prepausal word before ungrammatical pauses, there were few continuation rises in pitch, whereas 80 percent of the grammatical pauses were accompanied by a prior fundamental frequency rise of 10-40 kHz. Identifying the syntactic function of such hesitation phenomena can improve recognition performance by eliminating from consideration some of the hypotheses proposed by an acoustic recognizer. Results presented allow simple identification of filled pauses (such as uhh, umm) and their syntactic function.

A FRAMEWORK OF CONNECTIONIST NETWORK TOWARD SPEECH WAVEFORM CODING **c32**
Ying Cheng, Paul Fortier, and Denis Poussart *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The application of a connectionist or neural network to speech waveform coding is investigated. A connectionist network, which was primarily based on the adaptive resonant theory principle, was built as a codebook generating machine. A three-layer/multi-layer perceptron learned to encode and decode the speech wave form. The connectionist network was tested in simulation experiments by implementing machines for both 4k bits/s and 8k bits/s at an 8 kHz sampling rate and vector dimensions of 8. During the training procedure, 6680 vectors (6680 ms of speech) contributed to the codebook generation, resulting in two codebooks of size 2(exp 7) and 2(exp 8). The recovered speech proved to be highly natural and legible for both the 4k and 8k machines.

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The rate of oscillation of the vocal cords and its inverse value, the pitch period, are important speech features that are useful for speech analysis/synthesis, speech recognition, and speech coding. An automatic approach for the estimation of the pitch period in continuous speech is presented. The proposed approach considers the segmentation of the speech signal into homogeneous regions and the detection of segments that are generated by vocal cord oscillations prior to pitch estimation. The pitch period of voiced segments is estimated in the frequency domain using a maximum likelihood (ML) procedure. The estimated pitch period is chosen to maximize a likelihood function over the range of expected pitch periods. An efficient simplified realization of the generalized likelihood ratio segmentation method is also described.

SPEAKER-INDEPENDENT ISOLATED-DIGIT RECOGNITION USING NEURAL NETWORKS AND HIDDEN MARKOV MODEL **c32**
Michael McGuire, Diane Ingraham, and Vladimir Cuperman *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A speaker independent isolated-digit recognition system is described which incorporates neural networks for vector quantization (VQ) and postprocessing of VQ and hidden Markov model (HMM) decision information. Vector quantization was performed using word-based parameter specific codebooks generated with a frequency sensitive competitive learning (FSCL) training algorithm. A single-layer perceptron neural network was used to

increase recognition performance by postprocessing VQ distortion and HMM output probabilistic information. Experiments using both studio and telephone-line recorded databases demonstrate the FSCL VQ-HMM system without postprocessing achieves a recognition performance increase when compared to a previously developed VQ-HMM digit recognition system. With the addition of postprocessing to the FSCL VQ-HMM system, recognition performance was further increased. Author (CISTI)

TRENDS IN SOFTWARE RELIABILITY MODELING **c61**

Rudolph E. Seviora and Christian Brunelle (Bell Canada, Longueil, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The state of reliability engineering is much less advanced for software than for hardware. Software reliability models used for estimation or prediction strive to either model the growth in the reliability of the product whose faults are being removed from its past failure history, or to forecast the reliability of the software product before any operational experience is available. The current state of software reliability estimation and prediction and possible future trends are described. The assumptions used in typical models are listed and discussed. Most estimation models have the underlying assumption that a fault, if not removed, would cause failures to occur according to a Poisson process; recent research has shown that this is true only for first-time failures. A major trend is the adjustment of models to pragmatic realities of failure data collection and software life cycle. For prediction models, one trend is towards models whose data requirements are lower (coarser granularity models). Author (CISTI)

A NEW CLASS OF MULTI-FUNCTION TWO-RAIL TOTALLY SELF-CHECKING BASIC BUILDING BLOCKS **c64**

Zhi-Jian Jiang and R. Venkatesan *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new concept of strong morphic Boolean algebra is introduced. A new universal set of multi-function two-rail (TR) totally self-checking (TSC) basic building blocks (BBB) which implements a group of basic strong morphic operations is proposed. The proposed structures preserve the capabilities of fault indication (single or double error detection) and also facilitate normal logic operations. The logic representations of the TR error indication variable are 01 for logic 0, 10 for logic 1, and 00 or 11 for error indication. The new BBB are particularly useful and flexible in building TR-TSC logic functional circuits while they can still be used in building error correcting and/or error detecting circuits. Any arbitrary combinational logic can be implemented using the proposed BBB. As an example, a TR-TSC full adder with separate internal fault indication is presented. This cannot be achieved using the existing primitive operators. Author (CISTI)

Operating system mechanisms are explored which support system recovery from the failure of any one processor in a standard multiprocessor system. The mechanisms implemented allow existing operating system calls to be used. A history of messages is maintained for designated tasks. Only some tasks are backed up, so operation after a failure may be in a degraded mode. A synchronization operation limits the history which must be kept. A three-way atomic message protocol is needed to keep backups for both sender and receiver. A roll forward technique is used to recover the state of backed-up tasks. The design uses message passing primitives that support proprietors and administrators, which are useful abstractions for maintaining history and ensuring that variables shared between processors are protected and correctly updated for local access. A prototype based on the Harmony operating system was developed to demonstrate the major aspects of the design. Author (CISTI)

Single sideband (SSB) modulation is a special case of combined amplitude and phase modulation that results in suppresion of either the upper or lower sideband of the modulated signal. A study was carried out to combine the bandwidth efficiency of single sideband suppressed carrier transmission with the simplicity of detection offered by envelope detection as proposed by Hanson (1968). In the case of an analog message waveform this has been shown to be impossible, however for a digital data signal it is required only that the envelope have correct value at the sampling instant. Given this weaker constraint a data precoding/predistortion algorithm is proposed that may be applied in order to obtain a solution. The algorithm measures the squared error between the desired and predicted received levels for a given choice of transmitter inputs and determines a correction to the inputs based on the error gradient. The adaptive processor was able to achieve eye openings of up to 60 percent for single sideband suppressed carrier data signals. The best result used a table lookup to generate the initial input estimates, used two input streams, required knowledge of all data values affected by the block under optimization and considered error in the bits preceding and following the block under adaptation. INTERSYMBOL INTERFERENCE EFFECTS IN DIGITAL MATCHED FILTERS

Norman C. Beaulieu and Colin C. Climie *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The performance of digital matched filters is evaluated in the presence of intersymbol interference and loss of desired signal energy caused by prefiltering. The optimum filter, in a probability of error sense, is sought with regards to filter bandwidth and number of samples per symbol. The degradation factor, based on average error probability, is derived for some common lowpass filter characteristics. It is shown that previous methods are ill-suited to the problem. In some cases, improvement over previous methods is as much as 2 dB when the analogue matched filter is used as a basis for comparison. Author (CISTI)

FM INTERFERENCE IN RADIO NAVIGATION RECEIVERS [INTERFERENCE MF DANS LES RECEPTEURS DE RADIO NAVIGATION] **c04**

H. T. Huynh, J. M. Vezin, and D. Angers *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The azimuthal location receiver in an instrument landing system uses the 108-118 MHz frequency band which is adjacent to the FM broadcast band. With its low power (10 watts), the receiver would be strongly affected by the interference from the FM intermodulation provoked by two or three FM broadcast signals (interferences of type B1). Using a standard receiver with automatic gain control, the interference power/signal power ratio is computed at the interference threshold. The results show that the receiver is perfectly characterized only by its intermediate frequency stage bandwidth.

The worst case is noted when the intermodulation signal frequency coincides with the main carrier. The more the frequency difference increases, the more the system becomes tolerant. Author (CISTI)

ARCHITECTURES OF THE FREE SPACE OPTICAL INTERCONNECTS **c74**

Yun-Long Sheng *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Optical free space interconnects potentially offer high density, low power dissipation, flexibile solutions for pin out problems in very large scale integration (VLSI) chips. Two architectures of free space interconnects that are compatible with the VLSI environment are presented. One uses a retroreflective prism array to reduce the request for alignment accuracy and can be used for interconnections in a multichip module. Another uses integrated planar optics for intrachip interconnections. In the corner cube array the divergent signal beams from transmitters in the processing elements are colimated by a lens, reflected back by corner cubes, and converged into the photodetectors in the processing elements. Two optical elements useful for steering the signal beams in the integrated planar optical module are discussed: surface relief staircase profile gratings and micromirrors. The staircase profile surface relief gratings may be used for steering signals to zig-zag paths, and micromirrors made by mass transport procedures can provide array-to-array interconnections and large reflection angles. BALANCED ARROW MACH-ZEHNDER INTERFEROMETER **c35**

S. F. Yuen, J. Chrostowski, and B. A. Syrett *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new integrated passive interferometer having balanced dissimilar arms is studied. One arm of the interferometer consists of a conventional rib waveguide while the other arm is made using an antiresonant reflecting optical waveguide (ARROW). The large wavelength dependent chromatic dispersion of the ARROW allows the two arms of the device to be built with the same optical pathlength at any one wavelength resulting in a device which is insensitive to changes in ambient temperature. The device can be used as a sensor, a multiplexer/demultiplexer in wavelength division multiplexing, and a filter in frequency division multiplexing. The interferometer is very useful in sensing applications where large temperature fluctuations are expected. The inferometer's usefulness in this situation is due to its temperature insensitivity. OPTICAL PROCESSING IN PHOTOREFRACTIVE MEDIA **c74**

S. A. Boothroyd, L. Chan, P. H. Beckwith, and J. Chrostowski *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A beam of light can be made to interact with other light beams through a nonlinear response of an optical medium. The potential of photorefractive media in optical processing is demonstrated using barium titanate. A novel method is described whereby input scenes can be processed within the photoreactive medium response time by image subtraction and feature enhancement. Results are presented showing the interference of two coherent images having both a controllable phase difference and pixel registration between them. The two images are written into the barium titanate crystal via a spatial light modulator. Four-wave mixing phase conjugation is used to effect a process output image showing image subtraction, spatial differentiation, and digital optical logic OR and XOR operations. Author (CISTI)

CODED 64QAM USING A BINARY CONVOLUTIONAL CODE **c32**

Chintha Tellambura, Qiang Wang, and Vijay K. Bhargava *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Trellis coding combined with Viterbi decoding can achieve asymptotic coding gains up to 6 decibels in AWGN channels; however each signal constellation requires a different code. The design of 64-CQAM (coded quadrature amplitude modulation) with binary convolutionary code having transmission efficiency of 5 bits/symbol is considered as an alternative approach using existing Viterbi decoding with punctured codes. The standard rate 1/2 v equals 7 convolutional code is used with puncturing to increase the code rate to 5/6. Code words are mapped into channel symbols using Gray codes. All permutations were considered, and the optimum were selected. Both analytical and Monte Carlo simulation results are presented. Channel cut-off rate is evaluated for both unquantized and quantized channels proving that the performance loss due to quantization is negligible. The asymptotic coding gain of 64CQAM over uncoded 32AMPM is found to be 3.0 decibels, which is somewhat less than Ungerbock's best with the same complexity. Author (CISTI)

CAPACITY COMPARISON BETWEEN DIRECT SEQUENCE PSK AND MFSK SPREAD SPECTRUM SYSTEMS IN CDMA APPLICATIONS **c32**

Jun Wang and Abbas Yongacoglu *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

In most code division multiple access (CDMA) applications, the baseline system uses direct sequence (DS) phase shift keying (PSK) signals. Another possible direct sequence CDMA system which uses noncoherent orthogonal MFSK (frequency shift keying) signals has not received much attention. The capacities of direct sequence PSK and MFSK in spread spectrum (SS) systems are compared. Results show that for both systems, the asymptotic capacity at a certain value of bit error rate is inversely proportional to the required bit energy to noise density ratio. Since MFSK can be more power efficient than PSK, MFSK/DS-SS offers higher capacity when forward error correction (FEC) coding is not used. However, coherent PSK provides a larger capacity than MFSK when FEC coding is used. Author (CISTI)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An approach is described to the problem of building a three dimensional depth map of the ground sensed from an aircraft and computing the position of the sensing aircraft from a monocular sequence of aerial images. Specific solutions are presented for the aspects of camera calibration, image matching, and structure and motion estimation. Results from the calibration method show that correcting both radial and tangential distortions introduced by the lens system can bring about a substantial improvement. Image matching is performed by a region-based algorithm which is suitable for parallel implementation and produces dense displacement maps. Finally, the approach to the estimation problem is a so-called recursive-batch approach which is superior to conventional Kalmann filtering methods, while requiring only limited computational resources. A REAL-TIME INFRARED IMAGE PROCESSING TESTBED **c74**
E. Lithopoulos, J. Hodd, and E. Bender *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The development, implementation, and evaluation of an infrared target processor (TP) testbed is described. The testbed is capable of automatic real-time detection and tracking of targets in infrared imagery. Algorithms suitable for hardware implementation were first developed, tested, and evaluated in software and the ones with the best performance were implemented using Datacube's MaxVideo family of boards. The TP is capable of automatic target detection in infrared images, clutter/background target discrimination, target feature extraction and classification, and target tracking. A human interface allows the operator to bypass the TP and manually cue targets, and fully integrates all TP control functions and display in one station. The testbed is easily reconfigurable and capable of processing rates equivalent to thousands of millions of instructions per second.

MEMORY BASED VISION: A NEW CONCEPT **c63**
Martin P. Levesque and Auguste Blanchard *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

The main goal of the memory based vision (MBV) paradigm is to provide a strategy to obtain the best knowledge and perception of an object of interest from every observation made of this object during the past and present. This requires a memory process that can compare the current observations with former ones. The purpose of this process is to build a representation of the selected object(s) and complete or update it using the current input. The application of MBV to a visualization problem results in a selective and associative vision system: selective because the system extracts only the information related to the object of interest, and associative because the system merges every available object observation into a coherent representation set. This leads to a system able to provide an updated object representation that contains more information than that only available in the current observation. Furthermore, it would be conceivable to extend the memory process to include observations done during other experiments and object models. Examples are presented of MBV applied to noise reduction, background suppression, super resolution, three dimensional estimation, and object removal. Author (CISTI)

An analysis is presented of an adaptive position control which allows a 4-axis SCARA robot to follow a trajectory expressed in Cartesian coordinates. The control stability is studied with the aid of a Liapunov function, which also allows deduction of a law of adaptation of the control parameters. A numerical simulation carried out utilizing the MATLAB program shows the precision of this adaptive control. A comparison with the precision obtained by a simple PD control shows the adaptive control's clear superiority.

A ROBUST ADAPTIVE CONTROL DESIGN FOR FLEXIBLE JOINT MANIPULATORS **c63**
K. Khorasani *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The problem of designing a robust adaptive control strategy for a flexible joint robot manipulator is considered. By utilizing the concept of integral manifolds, reduced-order models of the flexible system are obtained. This enables development of adaptive control schemes for the flexible full-order system at the reduced-order level, which otherwise would be difficult to obtain for the full-order system due to ill conditioning and the problem of dimensionality. Two common adaptive control strategies are examined: adaptive inverse dynamics, and the Slotine and Li algorithm (although any other algorithm can be treated similarly). It is shown how these standard rigid adaptive control techniques may be generalized and improved upon for successful application to a flexible joint manipulator. Author (CISTI)

QUADRATURE BIORTHOGONAL MODULATION **c32**
S. Fleisher, Shou-Xing Qu, and Shalini Periyalwar *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A digital modulation method based on quadrature carrier multiplexing of two N-dimensional biorthogonal signal sets is proposed. One embodiment of the proposed scheme, referred to as quadrature frequency/phase modulation (QFPM), is discussed in detail. QFPM results when two NFSK/2PSK (frequency shift keying/phase shift keying) signals are quadrature carrier multiplexed, and its bandwidth efficiency is doubled as compared to that of the constituent NFSK/2PSK signals. Quadrature PSK (QPSK) and recently proposed Q2PSK are special cases of QFPM when N=1 and N=2, respectively. It is shown that the bandwidth efficiency of QFPM under certain conditions (such as for a signal set size of M=16) is the same as that of quadrature amplitude modulation (QAM), while the power efficiency of the former is significantly better. These features,

combined with a constant-energy property and self-synchronization capability, suggest that the proposed modulation scheme is of practical interest.

ENCODING AND DECODING QUASI-SPHERICAL SIGNAL SETS **c32**

Paul Fortier *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Recent methods for coded modulation are based on multidimensional signal sets. Moreover, it is well known that a moderate gain can be achieved using specially shaped signal sets. A method for generating quasi-spherical signal sets to be used with coded modulation schemes is characterized. The method has the advantages of requiring a small number of computations. Shell construction is best used when the number of dimensions is about 20. The decoding procedure is described, as well as an alternative encoding procedure. Author (CISTI)

THE APPLICATION OF SAMPLE VECTOR SELECTION TO ADAPTIVE NULLING: PERFORMANCE COMPARISON FOR TECHNIQUES COMBINING GRAM-SCHMIDT ORTHOGONALIZATION WITH AVERAGING **c32**

Mylene Toulgoat and Ross M. Turner *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Adaptive antenna nulling is computationally demanding. New computationally efficient algorithms are presented for adaptive nulling based on the application of the Gram-Schmidt orthogonal ization to a selected set of data vectors which are in some sense the best vectors for estimating the jammer subspace. The performance of these algorithms is demonstrated as a function of the computational load versus the achieved output signal to noise plus jammer ratio and compared to the performance of the sampled matrix inversion technique. It is shown that the new algorithms perform better than the sampled matrix inversion method, requiring fewer computations when the ratio of the number of jammers to the array size is small. A FOUR-BAND INFRARED DATA ACQUISITION FACILITY FOR SIGNAL PROCESSING DEVELOPMENT **c74**

Benoit Montminy *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A four-band infrared data acquisition facility is reviewed, describing the internal operation of the multiband electro-optical scanner that collects the infrared scene radiation and the real-time computer that acquires the data. The data acquisition procedure and the format of the stored data are detailed and the use of the system as a tool for developing and demonstrating signal processing algorithms is discussed. An original experiment is introduced which will be made possible using the data acquisition facility. This experiment is the generation of false color infrared images for enhancing the target recognition capability of infrared systems. These images exhibit colors that depend on the ratio of the signal amplitude in different spectral bands, as opposed to the pseudocolor infrared images in which the intensity of the radiation is simply color coded.

TRAJECTORY COMPUTATIONS FOR AN IMPROVED CINETHEODOLITE TRACKING SYSTEM **c61**

Jean-Pierre Ardouin *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A new cinetheodolite tracking system has been developed for the Primrose Lake Evaluation Range in Alberta. This system improves the range's tracking abilities by providing different types of trajectories to slave the cinetheodolites in real time with new improved digital control algorithms. When the cinetheodolite operators need help, they can select any of these trajectories for slaving help and add corrections to them. The first type of trajectory is obtained by filtering radar coordinates with an alpha-beta filter. A second type of trajectory is based on a least squares solution of the cinetheodolites' pointing angles smoothed by an alpha-beta filter, and another type of trajectory is based on models of bombs or rockets. The different parts of the new tracking system are described, with emphasis on the trajectory computation algorithms. Some of the results obtained from the new system are illustrated to demonstrate its accuracy.

SIGNAL PROCESSING AND TARGET DISCRIMINATION ALGORITHMS FOR A ROSETTE SCAN TRACKER **c32**

Andre Morin *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 5 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A prototype of an infrared rosette scan tracker has been developed to evaluate the immunity of this type of tracker against decoys which can be deployed from a target aircraft. The performance of the tracker depends on the signal processing and the target discrimination algorithms employed to control the tracker. Because of the low resolution of the resulting target image, the rosette scanner does not have the ability to recognize the targets by their shape characteristics. In addition, targets which are too close appear simultaneously in the tracker instantaneous field of view. These targets are then detected in one single pulse signal. To prevent the tracker from breaking its lock onto its target, the transients in amplitude and width of the selected pulses are detected when decoys are deployed from the target. The occurrence of such transients initiates the computation of the drift between the estimated target position and the center of the pulse for the two axes to determine the direction in which the decoy was deployed. The performance of this processing technique is illustrated and some improvements are suggested. Author (CISTI)

RADAR IMAGING OF MOVING TARGETS **c32**

Yves deVilliers *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Eng neering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A radar technique utilizing frequency modulated continuous waves is being investigated as a means to identify in-flight targets. Special signal processing softwares were developed to obtain a radar image of the targets in free flight. The signal processing technique used to obtain the radar image is described. This technique can be divided into three parts. First, the program tracks the position of the target according to time. Secondly, the program computes the mean position, the mean velocity, and the mean acceleration of the center of gravity of the target. A correction of the displacement of the target is made from this information. Finally, the radar image is computed. This signal processing technique has been verified on real munitions in free flight. Radar images produced during that test are illustrated. Author (CISTI)

AN ALGORITHM FOR THE INTERFERENCE DETECTION AMONG POLYGONAL SURFACES **c63**

Clemont Dupuis and Caroline Ricard *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The problem of avoiding collisions when operating on computer models of physical objects is central to model-based manipulation systems. A geometric component which can detect collisions between the manipulator and objects in the workspace and plan collision-free paths is essential in robotics. An efficient algorithm is presented for the detection of intersections among polygonal objects in fixed positions (static interference checking), based on the divide and conquer paradigm. A new mean is proposed to minimize the number of pairs of polygons which should be examined for intersection analysis. The proposed algorithm has been implemented, tested, and compared to the algorithm of Boyse (1979). Empirical evidence has confirmed its theoretical claim to efficiency. Author (CISTI)

STRATEGY FOR MOTION OF A MOVING BODY OF QUASI-POLYGONAL FORM WITHIN A POLYGONAL SPACE [STATEGIE DE MOUVEMENT D'UN FORME QUASI-POLYGONALE DANS UNE SCENE POLYGONALE] **c63**
Clement Gosselin and Moufid Karray *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p In FRENCH (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

An algorithm is presented for resolving the problem of the motion of a moving body within a space containing many polygonal obstacles. It is proposed to find, if it exists, a continuous trajectory connecting two positions of the moving body. Along this trajectory, the body must not interfere with an obstacle. The geometry of the moving body is rectangular with two circular ends. The algorithm reduces the study of the movement of this geometry to a study of the movement of a bar within a quasi-polygonal space. The obstacles are augmented to have a polygonal form with rounded corners. The critical curves corresponding to this type of obstacle are derived and their utilization in the planning of a trajectory is demonstrated with the aid of an example. The notion of a connection graph is finally introduced to aid in planning the trajectory, eliminating return paths, and removing useless movements. Author (CISTI)

Analytic solutions are presented for the problem of planning trajectories for a certain type of robotic manipulator working in an environment encumbered by obstacles. The proposed method is based on obtaining analytic expressions describing the limits of the space attainable within the articulation space. These expressions will then render possible the detection of collisions while working directly in the articulation space, with the help of simple inequalities. A plane manipulator with two degrees of freedom is utilized as an example with the object of verifying the proposed method. Author (CISTI)

A recursive procedure for obtaining a (2 to the power n)-state extended Gilbert-Elliott fading channel model suitable for n-bit block codes is described. The extended model may be used for numerical assessment of the throughput of a variety of popular automatic repeat-request schemes used over fading channels such as those encountered in mobile communications systems. Computationally efficient lower and upper performance bounds are also developed for low memory fading channels. It is found that the throughput of the stop-and-wait protocol exhibits a maximum; therefore, there exists an optimum codeword length for this automatic repeat-request scheme. Author (CISTI)

SOME BEST RATE 1/p AND RATE (p-1)/p SYSTEMATIC QUASI-CYCLIC CODES OVER GF(3) AND GF(4) **c64**
T. Aaron Gulliver and Vijay K. Bhargava (Victoria Univ., British Columbia.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The class of quasi-cyclic (QC) codes has been proven to contain many good codes. To date the known QC codes are largely binary codes of the form 1/p and (p-1)/p constructed from circulant matrices. These results are extended to QC codes over GF(3) and GF(4). Good codes are constructed using integer linear programming and heuristic combinatorial optimization techniques. Many of these codes attain the best possible distance for any linear code with the same parameters, and several improve the maximum known minimum distances for linear codes. The link between power residue (PR) codes and QC codes is exploited as a means for constructing new QC codes and to initialize the construction algorithm. The minimum distance for the PR codes and the maximum known distance for the QC codes are tabulated. Author (CISTI)

PERFORMANCE OF RS CODES IN LOGNORMALLY SHADOWED RICIAN CHANNELS
Chokri Trabelsi and Abbas Yongacoglu *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The performance of Reed-Solomon (RS) codes with binary phase shift keying transmission is determined for a class of fading models for land mobile satellite communications. The fading model has the structure of a Rician model except that the line-of-sight component is subjected to a lognormal transformation. By exploiting the statistical characteristics of the multipath fading and shadowing, an effective coding/interleaving scheme is proposed. Author (CISTI)

ON THE CAPACITY OF (T,U) PERMUTATION DECODING METHOD **c64**
Jia Ming, Anader Benyamin-Seeyar, and Le-Ngoc Tho *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Error-trapping decoding techniques are attractive due to their simple structure. Since 1962, several improved error-trapping methods have been devised in an effort to extend the capability and effectiveness in decoding multiple error correcting cyclic codes. Prange (1962) and MacWilliams (1964) introduced a (T,U) permutation group applied to this error-trapping decoding strategy by making use of a set of code-preserving permutation to obtain k error-free positions from which the rest of the code word could be reconstructed. Recently, exact lower bounds on the code length n for (n,k,t) cyclic codes have been found by using two-step and three-step (T,U) permutation groups. A study is presented on the relationship between the code parameters n, k, t, and the number of permutation steps. Equations representing the exact relations between the code parameters and the number of steps are derived. Some examples are given of the capability of (T,U) permutation decodable cyclic codes. The adaptive decoding algorithm, which is a modification of the Viterbi algorithm (VA), is presented. Compared to the VA, the average number of survivors is reduced while the degradation in error performance is negligible. Just like the VA, this algorithm is self-synchronizing and can recover the transmitted path even if it is not among the survivors. It is shown that codes with a constraint length K up to 10 can be used while maintaining an average complexity similar to the VA with K = 7 but with an improved bit error performance. The distribution of the computational effort is exponential, leading to a modest size of the input buffer and hence, a small probability of outflow. Author (CISTI)

BIDIRECTIONAL ALGORITHMS FOR THE DECODING OF CONVOLUTIONAL CODES OVER MEMORYLESS CHANNELS **c61**

Jean Belzile and D. Haccoun *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

New bidirectional multiple-path tree searching algorithms for the decoding of convolutional codes are presented. These suboptimal decoding algorithms, suited for long memory convolutional codes, use several paths, all of equal length, in a bidirectional breadth-first tree searching manner. Computer simulations using rate 1/2 codes with M = 32, 64, and 128 paths, show that a coding gain of 1 dB at a bit error probability of 10 to the minus 5 power can be achieved compared to Viterbi decoding using the same number of paths over a memoryless binary symmetric channel.

AN ADAPTIVE METHOD FOR GROUP DELAY COMPENSATION USING SWITCHED CAPACITOR FILTERS

C. S. Gargour, F. Ramachandran (Concordia Univ., Montreal, Quebec.), N. Batani, and T. Wong *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The importance of linear phase and constant group delay filtering is well recognized in the processing of signals related to different types of applications such as telecommunications and image processing. An adaptive method for the approximate group delay compensation in the analog domain is presented. The method is best suited for switched capacitor implementation. A theoretical analysis relating to the proposed method is given which refers to transfer functions fulfilling certain conditions. The system used to carry out the method includes a filter having the specified frequency responses, a compensation filter with specified transfer functions, an analog signal processing block, and a delay unit. The system was built and tested for the previously determined transfer functions. The results indicate that the proposed method is best suited for group delay compensation over a narrow bandwidth of frequency components having a narrow magnitude spread. Author (CISTI)

AN INSENSITIVE ALGORITHM FOR TEMPLATE MATCHING WITH CORRELATION **c61**

Zhen Mu, W. H. Lehn, and A. Wexler *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Template matching is an important approach used in image processing and computer vision to identify a certain pattern in a given image by comparing the grey levels between the selected pattern and a known pattern or template. An improved algorithm is presented for template matching with correlation to eliminate its sensitivities to scale and rotation of a segment. Comparisons are also made to template matching with Fourier transform. Tests demonstrate the efficiency and simplicity of the algorithm. The conditions and limitations of realizing insensitive algorithms for template matching with correlation are discussed. For segments of simple shape, the algorithm works quite efficiently and the correct results can be expected. For segments of complicated shape, this algorithm shows its low sensitivity in scale. The algorithm can be used when a segment and a template differ only in their scales and in the orientation of their main axes. Author (CISTI)

WIDEBAND SOURCE LOCATION IN TWO-DIMENSIONAL ARRAY PROCESSING **c32**

Jing-Yun Li and Patrick Yip *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A method suitable for two-dimensional wideband source location is presented. The method has high resolution and is established on the basis of autoregressive spectral estimation. The algorithm relies on a two-dimensional frequency dependent vector model, which can be decomposed into two one-dimensional structures. The method is reviewed for the case of a linear array, and parameter estimators are determined for a two-dimensional array. The selection of basis functions and the procedures used for smoothing are then described, and some simulation results are included. The analysis shows that sine functions, as a set of basis functions, can generate less perturbation, simplify the frequency combination, and decrease the complexity of computation. In comparison with signal subspace methods, the proposed algorithm can work in the case of only one snapshot. Author (CISTI)

ON COEFFICIENT QUANTIZATION AND COMPUTATIONAL ROUNDOFF EFFECTS IN FREQUENCY INTERPOLATION FILTER BANKS

Gen-Zao Zhang and W. F. McGee *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

Frequency interpolation filter banks have been presented as a new class of digital filter banks useful in speech and acoustics signal processing. The effects of filter coefficient quantization and computational roundoff on filter bank performance are studied for the case of fixed point arithmetic. The parameter sensitivity formulae of the filters in the bank are derived and discussed. The frequency response distortion and pole position change caused by finite word length implementation of the filter coefficients and zeroes of the bank are examined. White noise models are applied to analyze the effects of filter bank arithmetic roundoff, and the noise powers at filter outputs are calculated by numerical integration. Author (CISTI)

APPLICATIONS OF PLANAR NEAR-FIELD MEASUREMENTS TO ELECTROMAGNETIC RADIATION AND INTERFERENCE PROBLEMS **c32**

V. Betz, N. P. East, and A. Sebak *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)

Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

A simple system is described which finds the far-field radiation pattern of an antenna via the probe-corrected planar near to far-field transformation. An efficient method to obtain far-field data from near-field measurments based on a two-dimensional fast Fourier transform is presented. The practical aspects of the system, namely the type and quantity of field data required are discussed, as well as the design of the probe and data acquisition systems. The system is then used to find the far-field radiation patterns of

two antennas, a pyramidal horn and a planar microstrip array. Good agreement is obtained with patterns measured on a far-field range.

STUDY OF TE(1-DELTA) MODE IN OPEN DIELECTRIC RESONATORS BY A FINITE DIFFERENCE TIME DOMAIN METHOD **c32**
Ying Shen, Ke-Li Wu, Zhi-Qiang Bi, and John Litva *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The frequency resonant characteristics of axially symmetric dielectric resonators, the basic constituent elements of microwave integrated circuits, have previously been analyzed using several frequency domain approaches. The finite difference time domain (FDTD) method is proposed as an alternative approach. A numerical procedure based on the FDTD method and Mur's absorbing boundary condition is used to calculate the resonant frequencies of the TE(01-delta) mode for various open dielectric resonator structures. The calculated frequencies are compared with available experimental and published results. These comparisons demonstrate that the FDTD approach is a powerful tool for the modeling of arbitrary dielectric resonator structures with rotational symmetry. Author (CISTI)

ON THE RELATIONSHIP BETWEEN SPECTRAL DOMAIN APPROACH AND METHOD OF LINES **c64**
Da-Gang Fang, Hai-Qing Wu (Laval Univ., Quebec.), and Gilles Y. Delisle (Laval Univ., Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The method of lines was introduced to the field of microwave technology and was initially applied to the analysis of the dispersion characteristics of planar waveguide structures. This method can now be extended to include conductor thickness, dielectric, conductor losses, anisotropic substrates, and even non-rectangular boundaries. Some problems with the method of lines are discussed. First, a comparison is made between the two different methods introducing the method of lines, namely the separation of variables and the orthogonal transformation method. The agreement between the two methods yields the necessary knowledge to use the results in the method of lines. The relationship between the spectral domain approach and the method of lines is then presented. This relationship facilitates a better understanding of both methods and is helpful for transferring one technique to the other. As an example, the spectral domain immittance approach is introduced to the method of lines to provide a simple formulation and the theory is verified by comparison with the formulae developed by Nam, Ling, and Itoh (1989). CONTROL OF MULTIPLE ROBOT MANIPULATORS WITH OPTIMAL FORCE DISTRIBUTION **c63**
S. Kalaycioglu *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 3 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The control aspects of multiple robot manipulators with optimal load distribution are investigated. An analysis of the load distribution problem for coordinating two PUMA 560 robots handling a single payload is carried out and an optimal load sharing algorithm is applied. In this algorithm, minimum (norm) joint torques and minimum contact forces are obtained by the minimization of a quadratic function associated with the joint torques and the force vectors of dual robot arms with the constraints of the robot system equations. The applied algorithm is not computationally intensive in comparison with the other existing algorithms described in the literature, and therefore, is very attractive for real-time applications. OPTIMAL CONTROL OF THE TIP OF A FLEXIBLE ARM **c63**
Jean-Claude Piedboeuf, Denis Dochain (Ecole Polytechnique, Montreal, Quebec.), Richard Hurteau (Ecole Polytechnique, Montreal, Quebec.), and Kaouthar Benameur (McGill Univ., Montreal, Quebec.) *In* Engineering Inst. of Canada, Canadian Conference on Electrical and Computer Engineering, Volumes 1 and 2 1991 4 p (For primary document see N94-22101 05-33)
Avail: Issuing Activity (Engineering Inst. of Canada, 2050 rue Mansfield, Suite 700, Montreal, PQ H3A 1Z2 Canada)

The control of the tip position of a flexible robot is investigated. A linear optimal control law was selected and designed, based on a linear model obtained by linearization of a nonlinear model. The performance of the control method has been evaluated on the original nonlinear model, which has been found very useful to emphasize important flexible features and nonlinear characteristics of the system. Comparison was also made with a PID regulator. It was found that the optimal controller can overcome the difficulties encountered by the PID regulator, especially the control problems due to the inherent non-minimum phase behavior of the flexible arm. Field-emission displays (FED's) offer the potential advantages of high luminous efficiency, low power consumption, and low cost compared to AMLCD or CRT technologies. An LLNL team has developed silicon-point field emitters for vacuum triode structures and has also used thin-film processing techniques to demonstrate planar edge-emitter configurations. LLNL is interested in contributing its experience in this and other FED-related technologies to collaborations for commercial FED development. At LLNL, FED development is supported by computational capabilities in charge transport and surface/interface modeling in order to develop smaller, low-work-function field emitters using a variety of materials and coatings. Thin-film processing, microfabrication, and diagnostic/test labs permit experimental exploration of emitter and resistor structures. High field standoff technology is an area of long-standing expertise that guides development of low-cost spacers for FEDS. Vacuum sealing facilities are available to complete the FED production engineering process. Drivers constitute a significant fraction of the cost of any flat-panel display. LLNL has an advanced packaging group that can provide chip-on-glass technologies and three-dimensional interconnect generation permitting driver placement on either the front or the back of the display substrate. Development of a high-temperature, superconducting, synchronous motor for large applications (greater than 1000 HP) could offer significant electrical power savings for industrial users. Presently 60% of all electric power generated in the United States is converted by electric motors. A large part of this power is utilized by motors 1000 HP or larger. The use of high-temperature superconducting materials with critical temperatures above that of liquid nitrogen (77 K) in the field winding would reduce the losses in these motors significantly, and therefore, would have a definite impact on the electrical power usage in the U.S. These motors will be 1/3 to 1/2 the size of conventional motors of similar power and, thus, offer potential savings in materials and floor space. The cooling of the superconducting materials in the field windings of the rotor presents a unique application of cryogenic engineering. The rotational velocity results in significant radial pressure gradients that affect the flow distribution of the cryogen. The internal pressure fields can result in significant nonuniformities in the

two-phase flow of the coolant. Due to the variable speed design, the flow distribution has the potential to change during operation. A multiphase-flow computer model of the cryogenic cooling is developed to calculate the boiling heat transfer and phase distribution of the nitrogen coolant in the motor. The model accounts for unequal phase velocities and nonuniform cooling requirements of the rotor. The unequal radial pressure gradients in the inlet and outlet headers result in a larger driving force for flow in the outer cooling channels. The effect of this must be accounted for in the design of the motor. Continuing improvements of the model will allow the investigation of the transient thermal issues associated with localized quenching of the superconducting components of the motor. DOE

CHEMICAL EQUILIBRIUM IN HIGH PRESSURE MOLECULAR FLUID MIXTURES
M. S. Shaw 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-36)
(DE93-040160; LA-UR-93-3185; CONF-930676-47) Avail: CASI HC A01/MF A01

The N(sub atoms)PT Monte Carlo simulation method has been reformulated to incorporate multiple species and chemical reactions with changes in total number of molecules. While maintaining a constant number of each type of atom, the number of molecules is changed by turning on and off the interactions of any particular molecular position with other molecules. Chemical reactions are allowed as a correlated move of atoms to different molecular locations. Equilibrium chemical composition is determined as an average over the simulation along with equation of state quantities. A large set of simulations has been made with the system N2 + O2 reversibly yields NO covering a wide range in P and T. Both Hugoniot states and the CJ point have been determined and are shown to be sensitive to the potentials between unlike species. DOE

Measurements of droplet dispersion and vaporization rates are carried out and compared with computational predictions. Droplet dispersion, mean axial velocity, and the axial autocorrelation function of the droplets are measured using a laser sheet technique. The experimental facility is modified to accommodate a true spray using an ultrasonic atomizer and droplets injected with a fluorescent dye. The computational part of the project is the development of a Large Eddy Simulation (LES) method for the turbulent jet. A LES-model for the unresolved scales of the flow is implemented into the Navier-Stokes solver. The results for filtered and unfiltered variables are compared to the experiments and improvement of the particle statistics due to the LES-model is found. DTIC

Although there are more unlike-pairs than like-pairs in detonation products, information on unlike-pair interactions is scarce at present. We describe how unlike pair-interactions involving dissociation products of CO and CO2 can be derived by means of an accurate statistical mechanical theory of mixtures and recent shock wave data of CO and CO2. We then extend this complex study further by interpreting shock data of liquid NO and N2 + O2 mixture. It was done by constraining the resulting potentials to agree with all available Hugoniot data of chemical species occurring in detonation products in a self-consistent manner. DOE

Work has been pursued, by application of the fundamental principles of chemical kinetics and fluid transport, on a 'proof-of-principle' for a novel oblique-detonation-wave-engine (ODWE) as an alternative to a mixing-controlled supersonic combustor. The concept involves the nonintrusive stabilization of a conical detonation wave. Laser technology permits the rapidly repeated pulsed deposition of energy at a fixed site on the axis of symmetry of a supersonically flowing, combustible mixture. Each pulse suffices for the direct initiation of a radially-, outwardly-propagating, Chapman-Jouguet detonation wave. The interaction of the individual spherical waves, as the periodic train is convected by the flow, results in a nonintrusively stabilized conical wave as the time interval between the very brief pulses decreases. The detonated gas may be expanded in a supersonic nozzle (of practical length) for discharge at ambient pressure, such that thrust is generated. Author (DTIC)

Optical measurement techniques are extremely useful in fluid mechanics because of their non-invasive nature. However, it is often difficult to separate measurement effects due to pressure, temperature and density in real flows. Using a variation of a Shack-Hartmann wavefront sensor, we have made density measurements that have extremely large dynamic range coupled with excellent sensitivity at high temporal and spatial resolution. We have examined several classes of flow including volumetrically heated gas, turbulence and droplet evaporation. DOE

FLUID DYNAMIC MECHANISMS AND INTERACTIONS WITHIN SEPARATED FLOWS Final Report
J. C. Sutton and A. L. Addy 9 Aug. 1993 213 p
(Contract DAAL03-90-G-0021)
(AD-A271037; UILU-ENG-93-4019; ARO-27558.14-EG) Avail: CASI HC A10/MF A03

The significant results of a joint research effort investigating the fundamental fluid dynamic mechanisms and interactions within high-speed separated flows are presented in detail. The results were obtained through primary emphasis on experimental investigations of missile and projectile base flow-related configurations. The objectives of the research program focus on understanding the component mechanisms and interactions which establish and maintain high-speed separated flow regions. The experimental efforts considered the development and use of state-of-the-art laser Doppler velocimeter (LDV) and particle image velocimeter (PIV) systems for experiments with axisymmetric and planar, two-dimensional models in subsonic and supersonic flows. The LDV experiments yielded high quality, well documented mean and turbulence velocity data for a variety of high-speed separated flows including the near-wake region behind a cylindrical afterbody in supersonic flow. The PIV experiments studied the effect of a base cavity in a two-dimensional, subsonic base flow and the mechanism of drag reduction for this configuration. Another experimental study considered the interaction occurring when a supersonic stream is separated by means of a second stream impinging the first at an angle (plume-induced separation). The results of these various studies were carefully documented in a series of journal articles, conference proceedings papers, and theses. The full text of the papers and thesis abstracts are included as appendices. DTIC

LINEAR AND NONLINEAR PSE FOR COMPRESSIBLE BOUNDARY LAYERS Final Report
Chau-Lyan Chang, Mujeeb R. Malik, Gordon Erlebacher, and M. Yousuff Hussaini Sep. 1993 47 p
(Contracts NAS1-18605; NAS1-19480; NAS1-18240; RTOP 505-90-52-01)
(NASA-CR-191537; NAS 1.26:191537; ICASE-93-70) Avail: CASI HC A03/MF A01

Compressible stability of growing boundary layers is studied by numerically solving the partial differential equations under a parabolizing approximation. The resulting parabolized stability equations (PSE) account for nonparallel as well as nonlinear effects. Evolution of disturbances in compressible flat-plate boundary layers are studied for freestream Mach numbers ranging from 0 to 4.5. Results indicate that the effect of boundary-layer growth is important for linear disturbances. Nonlinear calculations are performed for various Mach numbers. Two-dimensional nonlinear results using the PSE approach agree well with those from direct numerical simulations using the full Navier-Stokes equations while the required computational time is less by an order of magnitude. Spatial simulation using PSE were carried out for both the fundamental and subharmonic type breakdown for a Mach 1.6 boundary layer. The promising results obtained show that the PSE method is a powerful tool for studying boundary-layer instabilities and for predicting transition over a wide range of Mach numbers. Author

STABILITY LIMITS AND DYNAMICS OF NONAXISYMMETRIC LIQUID BRIDGES Annual Report No. 1, 19 Nov. 1992 - 18 Nov. 1993
J. Iwan D. Alexander, Andy Resnik, and William F. Kaukler 1993 29 p
(Grant NAG3-1384)
(NASA-CR-194706; NAS 1.26:194706) Avail: CASI HC A03/MF A01

This program of theoretical and experimental ground-based and low gravity research is focussed on the understanding of the dynamics and stability limits of nonaxisymmetric liquid bridges. There are three basic objectives to the proposed work: (1) to determine the stability limits of nonaxisymmetric liquid bridges held between non-coaxially aligned disks; (2) to examine the dynamics of nonaxisymmetric bridges and nonaxisymmetric oscillations of initially axisymmetric bridges (some of these experiments require a low gravity environment and the ground-based research will culminate in a definitive flight experiment); and (3) to experimentally investigate the vibration sensitivity of liquid bridges under terrestrial and low gravity conditions. THERMAL DILATION FIBER OPTICAL FLOW SENSOR Patent
Thomas G. Giallorenzi, inventor (to Navy) 4 May 1993 7 p Filed 30 Sep. 1991
(AD-D015926; US-Patent-5,208,650; US-Patent-Appl-SN-767189;
US-Patent-Class-356-345) Avail: US Patent and Trademark Office

A thermal dilation type optical flow sensor includes an optical heating source for heating a flowing fluid and a sensor disposed in a downstream direction from said heating source wherein the sensor includes a probe for varying a reflected light according to the temperature of the probe, a Michelson type interferometer for measuring the temperature of the probe

according to the phase of the reflected light, and a calculating device for determining the flow rate based on temperature of the probe, the distance between the heating source and the probe, and the amount of heat produced by the heating source. In an alternative embodiment, a thermal dilation type optical flow sensor includes a reflecting probe disposed in a flowing fluid for reflecting an incident light with a phase varied according to the probe temperature, an optical heater for heating the probe with a predetermined heat, and a calculating device for calculating a new rate based on the predetermined heat and the phase of the reflected light.

EHD ENHANCEMENT OF POOL AND IN-TUBE BOILING OF ALTERNATE REFRIGERANTS
M. M. Ohadi, S. Dessiatoun, A. Singh, and M. A. Fanni Aug. 1993 44 p
(Contract DE-FG02-91CE-23810)
(DE94-000787; DOE/CE-23810/17) Avail: CASI HC A03/MF A01

The electrohydrodynamic (EHD) is an active heat transfer augmentation technique which utilizes the effect of secondary motions generated through the application of an electrostatic potential to a dielectric fluid. Net result is better momentum and heat transfer between the fluid and the heat transfer wall through destabilization of the thermal boundary layer and better mixing of the fluid adjacent to the heat transfer surface. EHD enhancement of refrigerant/refrigerant oil mixtures heat transfer using the electrohydrodynamic (EHD) technique is the subject of a three-year experimental investigation in a project funded by the U.S. Department of Energy, effective June 1, 1993. For the interim period between November 1992 and June 1993 when the DOE funds became available, the Air-Conditioning and Refrigeration Technology Institute (ARTI) provided partial funding for our EHD research program with the aim of accomplishing three major tasks: (1) conduct a comprehensive search of the literature on EHD-enhanced, in-tube and external boiling heat transfer enhancement of alternate refrigerants; (2) design, fabricate, and instrument an in-tube, EHD-enhanced boiling/condensation test rig and perform preliminary testing of the setup; and (3) conduct experiments and document new findings on EHD-enhanced external boiling of alternate refrigerants/refrigerant mixtures in an existing pool boiling test rig apparatus. Description of tasks performed are described and results are discussed.

A COMPARISON OF TWO INCOMPRESSIBLE NAVIER-STOKES ALGORITHMS FOR UNSTEADY INTERNAL FLOW
N. Lyn Willtberger, Stuart E. Rogers, and Dochan Kwak Nov. 1993 25 p Sponsored by NASA. Washington
(RTOP 505-10-01)
(NASA-TM-108794; A-94007; NAS 1.15:108794) Avail: CASI HC A03/MF A01

A comparative study of two different incompressible Navier-Stokes algorithms for solving an unsteady, incompressible, internal flow problem is performed. The first algorithm uses an artificial compressibility method coupled with upwind differencing and a line relaxation scheme. The second algorithm uses a fractional step method with a staggered grid, finite volume approach. Unsteady, viscous, incompressible, internal flow through a channel with a constriction is computed using the first algorithm. A grid resolution study and parameter studies on the artificial compressibility coefficient and the maximum allowable residual of the continuity equation are performed. The periodicity of the solution is examined and several periodic data sets are generated using the first algorithm. These computational results are compared with previously published results computed using the second algorithm and experimental data.

SHOCK INDUCED CONDENSATION IN FLUIDS OF HIGH MOLAR SPECIFIC HEAT: SHOCK STRUCTURE AND RELAXATION [STOSSSTRUKTUR UND RELAXATION BEI STOSSINDUZIERTER KONDENSATION IN SUBSTANZEN HOHER MOLARER SPEZIFISCHER WAERME]
Michael Hermann 1993 131 p In GERMAN
(MPIS-106/1993; ETN-93-94839) Avail: CASI HC A07/MF A02

The possible influence of nucleation on the thickness of a shock front which induces condensation of a retrograde gas in the mean flow of a shock tube is investigated. Measurements with and without condensation in the mean flow were performed using an optical method, which utilizes the dependence of the reflection of light from the shock front on its thickness. Condensation was monitored by means of scattering and extinction of laser light. As a test gas perfluoro-n-hexane was used, which, due to its high molar specific heat, exhibits retrograde behavior. For suitable conditions the gas reaches a supersaturated state within the shock, which gives rise to nucleation. Rotational and vibrational relaxation are very short; they are completed within the shock front. Following calculations presented in the literature, nucleation and subsequent condensation can cause a broadening of the shock. However, if the time scale for nucleation is much larger than those to reach thermodynamic equilibrium one can expect a relaxation tail behind the shock. In the range of the experiments depicted, no influence of nucleation on the shock thickness is observed. Within experimental accuracy all experiments can be described by an approximate continuum model, where the influence of vibrational relaxation is accounted for by introducing a bulk viscosity, which is assumed constant over the experimental range. The observed scattering and extinction of light in experiments with condensation can be examined by estimation of nucleation and droplet growth.

PRINCIPLES AND APPLICATIONS OF OIL FILM INTERFEROMETRY FOR MEASURING WALL FRICTION FIELDS IN AIR FLOWS Ph.D. Thesis [UEBER DIE GRUNDLAGEN UND EINIGE ANWENDUNGEN DER OEFILMINTERFEROMETRIE ZUR MMSSUNG VON WANDREIBUNGSFELDERN IN LUFTSTROEMUNGEN]
Gerd Janke 1993 162 p In GERMAN Sponsored by DFG Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-95062) Avail: CASI HC A08

In the framework of thin layer interferences, it is shown that the optical components of oil film interferometry can be reduced to a simple experimental facility. A method for the presentation of interference fringe motion along wall streamlines in space time diagrams, which is based on a video camera and an image processing computer, is proposed. The partial differential equation for the deformation of oil film surface was derived with consideration of shear stresses, pressure gradients, gravity, and surface tensions and was considered by means of dimensional analysis and magnitude order estimations. For shear induced film motion a theory for analytical solution of the partial differential equation was developed, including film surface deformation with any initial conditions and wall shear stress distributions. Analogies between oil film and fluid motions were realized. Comparisons of measurements with Preston tube results show a very good agreement.

HEAD-ON COLLISION OF DROPS: A NUMERICAL INVESTIGATION
M. R. Nobari (Michigan Univ., Ann Arbor.), Y.-J. Jan (Michigan Univ., Ann Arbor.), and G. Tryggvason (Michigan Univ., Ann Arbor.) Nov. 1993 50 p
(Contract NCC3-233; NAG3-1317; RTOP 505-90-5K; NSF CTS-91-32140)
(NASA-TM-106394; ICOMP-93-45; E-8219; NAS 1.15:106394) Avail: CASI HC A03/MF A01

The head-on collision of equal sized drops is studied by full numerical simulations. The Navier-Stokes equations are solved for fluid motion both inside and outside the drops using a front tracking/finite difference technique. The drops are accelerated toward each other by a body force that is turned off before the drops collide. When the drops collide, the fluid between them is pushed outward leaving a thin later bounded by the drop surface. This layer gets progressively thinner as the drops continue to deform and in several of the calculations this double layer is artificially removed once it is thin enough, thus modeling rupture. If no rupture takes place, the drops always rebound, but if the film is ruptured the drops may coalesce permanently or coalesce temporarily and then split again.

PRESSURIZATION AND EXPULSION OF A FLIGHTWEIGHT LIQUID HYDROGEN TANK

N. T. VanDresar and R. J. Stochl Dec. 1993 11 p Presented at the 29th Joint Propulsion Conference and Exhibit, Monterey, CA, 28-30 Jun. 1993; sponsored by AIAA, SAE, ASME, and ASEE See also A93-49814

(RTOP 506-42-73)

(NASA-TM-106427; E-8269; NAS 1.15:106427; AIAA Paper 93-1966) Avail: CASI HC A03/MF A01

Experimental results are presented for pressurization and expulsion of a flight-weight 4.89 cu m liquid hydrogen storage tank under normal gravity conditions. Pressurization and expulsion times are parametrically varied to study the effects of longer transfer times expected in future space flight applications. It is found that the increase in pressurant consumption with increased operational time is significant at shorter pressurization or expulsion durations and diminishes as the duration lengthens. Gas-to-wall heat transfer in the ullage is the dominant mode of energy exchange, with more than 50 percent of the pressurant energy being lost to tank wall heating in expulsions and the long duration pressurizations. Advanced data analysis will require a multidimensional approach combined with improved measurement capabilities of liquid-vapor interfacial transport phenomena.

TURBULENCE MODELING FOR HIGH SPEED COMPRESSIBLE FLOWS Final Report, 16 May 1991 - 30 Jun. 1993

Suresh Chandra 1993 12 p

(Grant NAG1-1287)

(NASA-CR-194547; NAS 1.26:194547) Avail: CASI HC A03/MF A01

The following grant objectives were delineated in the proposal to NASA: to offer course work in computational fluid dynamics (CFD) and related areas to enable mechanical engineering students at North Carolina A&T State University (N.C. A&TSU) to pursue M.S. studies in CFD, and to enable students and faculty to engage in research in high speed compressible flows. Since no CFD-related activity existed at N.C. A&TSU before the start of the NASA grant period, training of students in the CFD area and initiation of research in high speed compressible flows were proposed as the key aspects of the project. To that end, graduate level courses in CFD, boundary layer theory, and fluid dynamics were offered. This effort included initiating a CFD course for graduate students. Also, research work was performed on studying compressibility effects in high speed flows. Specifically, a modified compressible dissipation model, which included a fourth order turbulent Mach number term, was incorporated into the SPARK code and verified for the air-air mixing layer case. The results obtained for this case were compared with a wide variety of experimental data to discern the trends in the mixing layer growth rates with varying convective Mach numbers. Comparison of the predictions of the study with the results of several analytical models was also carried out. The details of the research study are described in the publication entitled 'Compressibility Effects in Modeling Turbulent High Speed Mixing Layers,' which is attached to this report.

A PARAMETRIC STUDY OF HEAT TRANSFER WITHIN A PLANAR THERMOSYPHON

R. Clarksean and G. Phillips 1993 11 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993

(Contract W-31-109-eng-38)

(DE93-019546; ANL/FC/CP-78624; CONF-930830-28) Avail: CASI HC A03/MF A01

The results of a parametric study for a planar thermosyphon are presented. The thermosyphon consists of a 'U-shaped' geometry, with the center portion of the 'U' being a solid. The outer legs of the 'U' are the flow channels. One of the outer surfaces of a channel is held at a constant temperature. The remaining outer surfaces are considered adiabatic. The configuration described is characteristic of passive systems for radioactive waste storage and reactor safety systems. Parameters which are varied include the channel geometry, the thermal conductivity of the solid, and the Ra number. The average Nu number for the constant temperature surface decreases as the inlet channel width decreases, and as the thermal conductivity of the solid increases. A modified Ra number, defined as the Ra number divided by the length to gap ratio for the outer channel, is used in the paper. At low values of the modified Ra number, there is over an order of magnitude decrease in the average Nu number for a change in the inlet channel width from 1.0 to 0.25. But as the value of the modified Ra number increases for any inlet channel width, the average Nu number results approaches those of vertical parallel plates, independent of the inlet channel width and the thermal conductivity of the solid. The vertical parallel plate data is approached because the boundary layer flow near the heated plate is unaffected by the surface of the intervening solid.

A NOVEL SCHEME TO HANDLE HIGHLY PULSED LOADS WITH A STANDARD HELIUM REFRIGERATOR

D. S. Slack 30 Jun. 1993 9 p Presented at the International Cryogenic Engineering Conference and International Cryogenic Materials Conference, Albuquerque, NM, 12-16 Jul. 1993

(Contract W-7405-eng-48)

(DE93-019617; UCRL-JC-112599; CONF-930703-26) Avail: CASI HC A02/MF A01

Helium refrigerator performance degrades rapidly when it has to handle a varying or pulsed heat load. A novel scheme is presented to handle highly pulsed 4.5 K cryogenic loads with a standard helium refrigerator by isolating it from these pulses. The scheme uses a relatively simple arrangement of control valves, heat exchangers, and a storage dewar. Applications include pulsed tokamak machines such as TPX (Tokamak Physics Experiment) and ITER (International Thermonuclear Experimental Reactor). For example, the TPX (currently in the conceptual design phase in a DoE contract) requires an average 4.5 K refrigerator capacity of about 10 kW; however, pulsed loads caused by eddy current and nuclear heating will exceed 100 kW. The scheme presented here provides a method for handling these pulsed loads. Because of the simple and proven nature of the components involved and the thermodynamic properties of the helium, the system could be implemented for projects such as TPX or ITER with little or no development.

EXPERIMENTAL STUDY OF A SHOCK ACCELERATED THIN GAS LAYER

J. W. Jacobs, D. G. Jenkins, D. L. Klein, and R. F. Benjamin 1993 9 p Presented at the 19th International Symposium on Shock Waves, Marseille, France, 26-30 Jul. 1993

(Contract W-7405-eng-36)

(DE93-018354; LA-UR-93-2449; CONF-930788-2) Avail: CASI HC A02/MF A01

Planar laser-induced fluorescence imaging is utilized in shock-tube experiments to visualize the development of a shock-accelerated thin gas layer. The Richtmyer-Meshkov instability of both sides of the heavy gas layer causes perturbations initially imposed on the two interfaces to develop into one of three distinct flow patterns. Two of the patterns exhibit vortex pairs which travel either upstream or downstream in the shock tube, while the third is a sinuous pattern that shows no vortex development until late in its evolution. The development of the observed patterns as well as the growth in the layer thickness is modeled by considering the dynamics of vorticity deposited in the layer by the shock interaction process. This model yields an expression for the layer growth which is in good agreement with measurements.

HIGH-RESOLUTION NUMERICAL METHODS FOR COMPRESSIBLE MULTI-PHASE FLOW IN HIERARCHICAL POROUS MEDIA

J. A. Trangenstein 15 Mar. 1993 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-FG05-92ER-25145)

(DE94-000740; DOE/ER-25145/1) Avail: Issuing Activity (Department of Energy (DOE))

This is the first year in the proposed three-year effort to develop high-resolution numerical methods for multi-phase flow in hierarchical porous media. There are three main issues being addressed in this research. The first issue is computational efficiency. Field-scale simulation of enhanced oil recovery, whether for energy production or aquifer remediation, is typically

highly under-resolved. This is because rock transport properties vary on many scales, and because current numerical methods have low resolution. The second issue is effective media properties. Since porous media are formed through complex geologic processes, they involve significant uncertainty and scale-dependence. Given this uncertainty, knowledge of ensemble averages of flow in porous media can be preferable to knowledge of flow in specific realizations of the reservoir. However, current models of effective properties do not represent the observed behavior very well. Relative permeability models present a good example of this problem. In practice, these models seldom provide realistic representations of hysteresis, interfacial tension effects or three-phase flow; there are no models that represent well all three effects simultaneously. The third issue is wave propagation. It is common in the petroleum industry to assume that the models have the same well-posedness properties as the physical system. An example of this fallacy is given by the three-phase relative permeability models; they were widely assumed by the petroleum community to produce hyperbolic systems for the Buckley-Leverett equations, but later the mathematics community proved that these models inherently produce local elliptic regions. Since numerical methods must use the models for computations, oscillations that develop could erroneously be attributed to numerical error rather than modeling difficulties. During this year, we have made significant progress on several tasks aimed at addressing these issues. DOE

A fluid separator for separating particulate matter such as contaminates is provided which includes a series of spiral tubes of progressively decreasing cross sectional area connected in series. Each tube has an outlet on the outer curvature of the spiral. As fluid spirals down a tube, centrifugal force acts to force the heavier particulate matter to the outer wall of the tube, where it exits through the outlet. The remaining, and now cleaner, fluid reaches the next tube, which is smaller in cross sectional area, where the process is repeated. The fluid which comes out the final tube is diminished of particulate matter.

The present invention relates generally to the field of thermal transfer and, more specifically, to a direct-interface, fusible heat sink for non-venting, regenerable, and self-contained thermal regulation. A quick connect coupling includes a male and a female portion. The female portion is frozen in a container of solid-phase coolant fluid, i.e., water, so that passages in the housing are blocked by ice initially. The ice is melted by direct interface with liquid coolant fluid delivered from the male portion. The present invention has advantages in that the phase change material remains sealed at all times, including during regeneration. Also, it uses quick-disconnect couplings that allow the phase change material to completely fill the container and is easily handled in microgravity without spills, leakage, or handling of phase change material.

THE EFFECT OF TRANSVERSE CURVATURE ON THE FLUCTUATING WALL PRESSURE AND STRUCTURE OF BOUNDARY LAYER TURBULENCE

Stephen R. Snarski 19 Aug. 1993 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271868; NUWC-NPT-TD-10459) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This document consists of the text and viewgraphs of a paper presented at the ONR Workshop on Nonequilibrium Turbulence held at Arizona State University in Tempe, Arizona, from 10-12 Mar. 1993. This workshop was the first step of an ONR Accelerated Research Initiative (ARI) to establish the state-of-the-art for theory, computation, and experimentation relevant to turbulence in a nonequilibrium state, or, more generally, to turbulence in complex flows. The overall goal of the initiative is to understand the behavior of turbulence in such complex conditions in order to advance our prediction and control capabilities. When a cylinder in axial flow is sufficiently long and thin, the growth of the boundary layer results in its thickness exceeding the radius of the cylinder such that the three-dimensional effects due to transverse curvature cannot be neglected. With this condition, the wall of the cylinder provides less constraint on the outer flow and motion of eddies than is experienced in an equilibrium flat plate boundary layer introducing an avenue for enhanced inner-layer/outer-layer interaction and modified turbulence activity. In this paper, we present results of measurements of the fluctuating wall pressure and turbulent streamwise velocity in the turbulent boundary layer on a cylinder in axial flow to identify the coherent structures that contribute to the fluctuating pressure at the wall. Determining the influence of transverse curvature on the relationship between the wall pressure and velocity field allows examination of its effect on the structure of equilibrium boundary layer turbulence.

Various heat exchange apparatuses are described in which an oscillating flow of primary coolant is used to dissipate an incident heat flux. The oscillating flow may be imparted by a reciprocating piston, a double action twin reciprocating piston, fluidic oscillators or electromagnetic pumps. The oscillating fluid flows through at least one conduit in either an open loop or a closed loop. A secondary flow of coolant may be used to flow over the outer walls of at least one conduit to remove heat transferred from the primary coolant to the walls of the conduit.

NUMERICAL INVESTIGATION OF LAMINAR-TURBULENT TRANSITION IN TWO- AND THREE-DIMENSIONAL BOUNDARY LAYERS Ph.D. Thesis - Karslruhe Univ. [NUMERISCHE UNTERSUCHUNGEN ZUM LAMINAR-TURBULENTEN UEBERGANG IN ZWEI- UND DREIDIMENSIONALEN GRENZSCHICHTEN]

Michael Wagner Jul. 1992 114 p In GERMAN
(DLR-FB-92-36; ETN-93-94870) Avail: CASI HC A06/MF A02

Transition to turbulence in two and three dimensional boundary layers is investigated by temporal numerical simulations and linear stability analysis. Simulations which are adapted to a transition experiment reveal a marked influence of the relative initial amplitudes of stationary and fluctuating disturbances on the transition process. In the late stages of transition the stability characteristics of the deformed mean velocity profile differ significantly from the stability results obtained for the laminar flow. Temporal

simulation results could be related to the spatial disturbance development in the experiment and show a good agreement with measurements. Towards the end of transition the crossflow vortices, developing as a primary instability of the laminar flow, begin to break down. Comparably inexpensive simulations comprising only a few modes in the wall-parallel directions appear to be suitable for a quick preliminary transition estimation. ESA

TWO-POINT LASER DOPPLER VELOCIMETRY MEASUREMENTS OF LENGTH-TURBULENT SCALES Ph.D. Thesis [MESURE DES ECHELLES TURBULENTES DE LONGUEUR PAR VELOCIMETRIE DOPPLER LASER EN DEUX POINTS]

Hafedh Belmabrouk 1992 188 p In FRENCH

(ECL-92-12; ETN-93-94412) Avail: CASI HC A09/MF A02

A method for measuring the space correlation between the flow velocity and the length-turbulent scales is proposed. The flow velocity simultaneous measurements at two distant points allow to calculate the space correlation coefficient. The next step is the calculation of integral and Taylor scales. The effect of optical and electronic adjusting parameters on the correlation is analyzed. The following parameters are found to be fundamental: the dimensions of the measurement volumes; and the need to adjust an osculate parabola near the origin by the least errors squares method. Two correlation models are applied: a Gaussian curve defined by the accurate Taylor scale data; and a model determined by both integral and Taylor scales. ESA

MULTI-CPU PLASMA FLUID TURBULENCE CALCULATIONS ON A CRAY Y-MP C90

V. E. Lynch, B. A. Carreras, J. N. Leboeuf, B. C. Curtis, and R. L. Troutman (National Energy Research Supercomputer Center, Livermore, CA.) 1993 32 p Presented at the Supercomputing Conference on High Performance Computing and Communications, Portland, OR, 15-19 Nov. 1993

(Contract DE-AC05-84OR-21400)

(DE93-015425; CONF-931115-6) Avail: CASI HC A03/MF A01

Significant improvements in real-time efficiency were obtained for plasma fluid turbulence calculations by microtasking the nonlinear fluid code KITE in which they are implemented on the CRAY Y-MP C90 at the National Energy Research Supercomputer Center (NERSC). The number of processors accessed concurrently scales linearly with problem size. Close to six concurrent processors have so far been obtained with a three-dimensional nonlinear production calculation at the currently allowed memory size of 80 Mword. With a calculation size corresponding to the maximum allowed memory of 200 Mword in the next system configuration, it is expected to be able to access close to nine processors of the C90 concurrently with a commensurate improvement in real-time efficiency. These improvements in performance are comparable to those expected from a massively parallel implementation of the same calculations on the Intel Paragon. DOE

SYSTEM AND METHOD FOR CANCELLING EXPANSION WAVES IN A WAVE ROTOR Patent

Daniel E. Paxson, inventor (to NASA) 7 Dec. 1993 9 p Filed 26 May 1992 Supersedes N93-11172 (31 - 2, p 297)

(NASA-Case-LEW-15218-1; US-Patent-5,267,432;

US-Patent-Appl-SN-889003; US-Patent-Class-60-39.45;

US-Patent-Class-417-64; Int-Patent-Class-F02C-3/02) Avail: US Patent and Trademark Office

A wave rotor system that is comprised of a wave rotor coupled to first and second plates is described. Special ports are provided, one in each of the first and second end plates, to cancel expansion waves generated by the release of working fluid from the wave rotor. One of the expansion waves is reflected in the wave rotor from a reflecting portion and provided to the special port in the second end plate. Fluid present at the special port in the second end plate has a stagnation pressure and mass flow which is the same as that of the cells of the wave rotor communicating with such special port. This allows for cancellation of the expansion wave generated by the release of working fluid from the wave rotor. The special port in the second end plate has a first end corresponding to the head of the expansion wave and a second end corresponding to the tail of the expansion wave. Also, the special port is configured to continually change along the circumference of the second end plate to affect expansion wave cancellation. An expansion wave generated by a second release of working fluid from the wave rotor is cancelled in a similar manner to that described above using a special port in the first end plate. The cycle of operation of the wave rotor system is designed so that the stagnation pressure and mass flow of the fluid present at the special ports is the same so that the special ports may be connected by a common duct.

(ECL-92-42; ETN-93-94598) Avail: CASI HC A08/MF A02

Turbulent models which can be applied for the investigation of industrial mixing system are studied. A three dimensional (3D) code is developed in this framework. The hydrodynamics of the turbulent flow is computed using the standard k-epsilon model. Some corrections of the standard model are also analyzed when a string rotation rate is imposed to the flow. For the scalar transport modeling two approaches are studied: the first one is the classical Eulerian first order closure, and the second one is a Lagrangian stochastic modeling based on the computation of scalar field using the statistic of fluid particle trajectories in the flow. In order to carry out computations into complex geometries a finite element method was applied. A set of test cases concerning both hydrodynamical and thermal problems is performed for which a great number of experimental data is given in the literature. More particularly, the case of a 3D turbulent jet normal to a cross flow is studied. ESA

MODELING OF PARTICLE DISPERSION IN A STATIONARY ISOTROPIC HOMOGENEOUS TURBULENCE BY LARGE SCALE NUMERICAL SIMULATION Ph.D. Thesis [DISPERSION DE PARTICULES DANS UNE TURBULENCE HOMOGENE ISOTROPE STATIONNAIRE CALCULEE PAR SIMULATION NUMERIQUE DIRECTE DES GRANDES ECHELLES]

Emmanuel Deutsche 1992 239 p In ENGLISH and FRENCH Original contains color illustrations

(ETN-93-94604) Avail: CASI HC A11/MF A03

A study aimed at improving the understanding of physical phenomena in the transport of discrete particles placed in a turbulent field, and aimed at validating certain closure hypotheses using a model with Eulerian transport equations for two phases is reported. In order to model the turbulence in the dispersed phase and the interfacial transfer terms between the phases, the Eulerian approach is based on the Lagrangian description of particle movement which enables the theoretical analysis of particle transport through a homogeneous turbulence. The model used to simulate the turbulence and the method used to maintain the stationary turbulent fields are described. The problem of simulating particle trajectories is considered. Results of simulations of particle clouds (25,000 to 100,000) in stationary homogenous turbulence are presented. ESA

FORMULATION OF A NEXT-GENERATION INTERIOR BALLISTIC CODE Final Report, May - Dec. 1991

Paul S. Gough Oct. 1993 71 p

(Contract DAAA15-91-M-0073; DA Proj. 1L1-61102-AH-43)

(AD-A271539; PGA-TR-91-3; ARL-CR-68) Avail: CASI HC A04/MF A01

Two-phase flow interior ballistic codes, both one-dimensional and two-dimensional, have been developed over the last 20 years for the purpose of modeling the behavior of solid propellant gun propulsion systems. These codes have proven useful for explaining charge malfunctions and for studying possible remedies. Over the years, these codes have become

increasingly elaborate as more complex designs have been addressed and also as the depth of simulation has increased. However, charge designs involving liquid propellant or electrothermal-chemical propulsion remain largely outside the scope of the solid propellant codes and a number of separate codes have been developed for the simulation of these alternative propulsion schemes. As we look to the future, it is evident that the next generation of interior ballistic models will be required to address three-dimensional details of the flow inside the gun. Such models will be expensive to develop and it is, therefore, of great interest to assess the extent to which a single code can be formulated to treat all foreseeable propulsion schemes. In this report, we review the physical problems of current interest, as well as those anticipated in the foreseeable future. We review the models currently available to address these processes. We then discuss the architecture, of a possible next-generation code. This discussion addresses the formulation of the equations, the choice of solution algorithms, and the implications of the current trend toward massively parallel computing. DTIC

CHEMICAL REACTION FOULING MODEL FOR SINGLE-PHASE HEAT TRANSFER
C. B. Panchal and A. P. Watkinson (British Columbia Univ., Vancouver.) 1993 16 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019556; ANL/ES/CP-79376; CONF-930830-25) Avail: CASI HC A03/MF A01

A fouling model was developed on the premise that the chemical reaction for generation of a precursor can take place in the bulk fluid, in the thermal boundary layer, or at the fluid/wall interface, depending upon the interactive effects of fluid dynamics, heat and mass transfer, and the controlling chemical reaction. The analysis was used to examine the experimental data for fouling deposition of polyperoxides produced by autoxidation of indene in kerosene. The effects of fluid and wall temperatures for two flow geometries were analyzed. The results showed that the relative effects of physical parameters on the fouling rate would differ for the three fouling mechanisms; therefore, it is important to identify the controlling mechanism in applying the closed-flow-loop data to industrial conditions. LIQUID-PHASE CIRCULATION AND MIXING IN MULTICOMPONENT DROPLETS VAPORIZING IN A LAMINAR CONVECTIVE ENVIRONMENT Final Report, 15 Aug. 1992 - 31 Jul. 1993
Constantine M. Megaridis and Joseph T. Hodges 15 Oct. 1993 93 p
(Contract F49620-92-J-0476)
(AD-A272851; AFOSR-93-0828TR) Avail: CASI HC A05/MF A01

A combined theoretical/experimental study of internal circulation induced by surface rotation of mm-sized pendant droplets was completed. The study consistently revealed predictable helical three-dimensional circulation patterns that bear little resemblance to the two-dimensional toroidal internal flows established within droplets under axisymmetric convective conditions. The observed complex flow patterns suggested substantially enhanced liquid mixing rates, thus indicating that droplet spinning may be very important in practical situations involving droplet convective transport. In a parallel study, charged droplets up to 100 micrometers in diameter were stably levitated and exposed to uniform air streams with Reynolds numbers up to three. The evaporation rate of levitated dodecanol droplets was measured under quiescent conditions and followed the familiar d squared law. No detailed information could be obtained on internal circulation of levitated droplets impregnated with scattering or fluorescent agents. DTIC

A unique iodine vapor hypersonic flow facility for the study of nonequilibrium reacting flows has been developed and used in initial experiments. An important new computationally efficient theoretical approach to describing the energy exchange of iodine and other molecules during collisions has been formulated and applied to iodine. The transport properties of dissociating diatomic molecules have been studied and a potentially very significant phenomena appearing when a gas is partially dissociated has been identified. A Ph.D. thesis has been completed on experiments with the iodine flow facility. Several journal articles and meeting papers on both the experimental and theoretical work have been prepared. A second Ph.D. thesis is nearly complete on the design of parallel flow nozzles for nonequilibrium dissociating, vibrationally active iodine flows. DTIC

CHARACTERISTIC BASED METHODS FOR THE TIME-DOMAIN MAXWELL EQUATIONS Final Report, Jun. 1990 - Feb. 1991
J. S. Shang 9 Aug. 1993 51 p
(AD-A272973; WL-TR-93-3080) Avail: CASI HC A04/MF A01

Numerical procedures for solving the time-domain Maxwell equations based on the theory of characteristics were successfully developed. Both explicit and implicit methods were formulated by the time-central and spatial-windward algorithm to better describe wave motion. A new trapezoidal consistent implicit scheme was shown to be unconditionally stable for the linear initial value system and was able to generate numerical solutions comparable to those of the established explicit method. The formulation of the three-dimensional system including generalized coordinate system was completed but not explored. The present 2-D results on Cartesian frame demonstrated a potential for numerical efficiency improvement. DTIC

MEASUREMENT AND PREDICTION OF THE FLOW THROUGH AN ANNULAR TURBINE CASCADE M.S. Thesis
Gregory D. Thomas 2 Jun. 1993 81 p
(AD-A272530) Avail: CASI HC A05/MF A01

An annular turbine cascade was designed and manufactured for laser Doppler velocimetry and probe measurements in a small-scale rig. The purpose of the experiment was to determine the limitations of these measurements in a confined annulus, and to compare the experimental results with numerical predictions. Downstream probe surveys were conducted at a Reynolds number of 500,000. Total pressure and temperature measurements were taken upstream of the test section, and hub static pressure was measured downstream of the cascade. A two-dimensional laser anemometer was used to obtain preliminary velocity field measurements for code validation. The two main problem areas identified were the type of seeding material used and the configuration of the optical access window. Flowfield characteristics were predicted using a three-dimensional viscous code, which were then compared to experimental measurements. The comparison showed that the numerical simulator predicted well the general features of the flow field that were measured in the experiment. Recommendations are made which would improve the mapping of the velocity field for a more complete code validation. DTIC

LOW REYNOLDS-NUMBER TURBULENT BOUNDARY LAYERS Final Report, 14 Apr. 1989 - 30 Mar. 1993
Ting Wang 30 Jun. 1993 58 p
(Grant AF-AFOSR-0324-89)
(AD-A272011; AFOSR-93-0809TR) Avail: CASI HC A04/MF A01

An experimental investigation was performed to determine the Reynolds analogy factor and turbulent Prandtl number in the transitional and low-Reynolds-number turbulent boundary layer. A miniature three-wire probe was specially designed to measure the mean velocity and temperature profiles and the Reynolds stresses and heat fluxes. Tests were conducted over a heated flat wall with zero pressure gradient and three levels of streamwise acceleration: K = 0.07, 0.16, and 0.25 x 10(exp -6). Mean temperature profiles lagged in development compared to the mean velocity profiles and the values of the Reynolds analogy factor, 2St/Cf, in the late-transition and early-turbulent regions were lower than the values known to apply to the high-Reynolds-number turbulent flow. The profiles of Reynolds cross-stream heat flux showed negative values in the near wall region. The region of negative vt narrowed as the flow proceeded downstream. These negative values of vt in a flow with a negative mean temperature gradient result in negative eddy thermal diffusivity and negative Pr(sub t). It is speculated that the negative values might be caused by the size of the sensor and the three-dimensional behavior of transition. A conditional sampling technique was utilized to separate the flow into turbulent and non-turbulent portions. Detailed flow and thermal structures were investigated. DTIC

N94-21531# Lawrence Livermore National Lab., CA.
DIRECT SIMULATION OF SHOCK-INDUCED MIXING LAYER
J. A. Greenough and J. B. Bell Mar. 1993 12 p Presented at the 4th International Workshop on the Physics of Compressible Turbulent Mixing, Cambridge, United Kingdom, 29 Mar - 1 Apr. 1993
(Contract W-7405-eng-48)
(DE93-040498; UCRL-JC-112208; CONF-9303126-9) Avail: CASI HC A03/MF A01

The interaction of a shock wave with a dense fluid layer in three dimensions is investigated using direct numerical simulations. The underlying numerical method is a second-order Godunov scheme. This is coupled to an implementation of Adaptive Mesh Refinement which is used to manage the hierarchical grid structure. An anomalous shock refraction is formed as the initiating shock wave impinges on a quiescent thin dense gas layer. One of the two resulting centered waves from the refraction, the contact surface, serves as the site for initial deposition of primarily spanwise vorticity and represents the primary mixing layer instability. The other wave, the transmitted shock wave, through repeated interactions with the free-surface, forms a cellular structure within the dense layer. The initial interaction introduces three dimensional perturbations onto the slip surface. These perturbations are selectively enhanced, due to favorable velocity gradients over part of the cellular structures, and form large-scale counter-rotating streamwise vertical structures. The structures characterize the secondary instability of this mixing layer. These vortices are quite unstable and transition to small-scales within a distance spanned by two of the cellular structures behind the initiating shock. The transition location has been verified in physical experiments. The fine-scale structure contains evidence of hairpin vortices. The evolution of a conserved scalar is used to monitor mixing progress. Increases in the rate of mixing are directly tied to intensification events associated with the streamwise vortices. Overall the large-scale streamwise structures provide an efficient mechanism for mixing the light and dense fluids. Analysis of time-series data from the calculation shows evidence of what are termed energetic small scales. This is the characteristic signature of the hairpin vortices undergoing intensification. A NOTE ON SINGULARITIES CAUSED BY THE HYDRODYNAMIC DISPERSION TENSOR
Ron A. Trompert Jan. 1993 9 p Sponsored by Ministry of Economic Affairs, The Hague, Netherlands
(CWI-NM-R9302; ETN-94-94704) Copyright Avail: CASI HC A02/MF A01

A study showing that the equation describing transport in a porous medium is not uniquely defined in points of the domain where the velocity of the fluid is zero is presented. This is due to the fact that the hydrodynamic dispersion tensor is defined as a not sufficiently differentiable function of the fluid velocity. The implications of this non smoothness for the numerical simulation of fluid flow and transport in porous media is discussed. ESA

LOCAL UNIFORM GRID REFINEMENT AND BRINE TRANSPORT IN POROUS MEDIA WITH INHOMOGENEITIES
Ron A. Trompert Nov. 1992 33 p Sponsored by Ministry of Economic Affairs, The Hague, Netherlands Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(CWI-NM-R9224; ETN-94-94699) Copyright Avail: CASI HC A03

The application of an adaptive grid method is discussed for a mathematical model for unsteady flow, coupled with transport of brine in porous media with inhomogeneities in two space dimensions. When the concentration of salt is large, the salt concentration profile in brine transport problems can show locally large gradients in space and in time. For this reason an adaptive grid method was chosen to solve these problems. A method based on local uniform grid refinement, where integration takes place on a series of nested, local uniform finer and finer subgrids, is considered. These subgrids are created up to a level of refinement where sufficient spatial accuracy is reached and their location and shape is adjusted after each time step. The space domain is considered to be a rectangle and all grids in use are uniform and cartesian. The interfaces, caused by the inhomogeneities, are assumed to coincide with cell edges in the numerical approximation. Special conditions are applied, connecting the solutions on both sides of the interface. These interface conditions involve continuity of fluxes across the interfaces. The mesh refinement process and the variabe time stepsizes are controlled by heuristic error monitors. The performance of the method is illustrated by two example problems. ESA

SURFACE PATH LINES IN PLANE STOKES FLOW DRIVEN BY CAPILLARITY
R. W. Hopper 3 May 1993 11 p
(Contract W-7405-eng-48)
(DE93-041277; UCRL-ID-114105) Avail: CASI HC A03/MF A01

Consider the free creeping viscous plane flow in a region, bounded by a simple smooth closed curve and driven solely by surface tension. The shape evolution may in principle, and often in practice, be described by a time-dependent mapping z = Omega(zeta,t) of the unit circle, conformal on absolute value of zeta less than or equal to one. It is shown that the path lines of fluid elements at the surface are determined by a first-order ordinary differential equation involving Omega(zeta,t), together with an initial condition. Typically, this must be integrated numerically. Velocities are not needed. The analogous theory for maps from the half-plane imaginary part

of zeta greater than or equal to zero is presented. Surface path lines of a collapsing elliptic hole, in two reference frames, are calculated. DOE

(Contract DE-AC11-89PN-38014)
(DE93-040657; WAPD-TM-1629) Avail: CASI HC A03/MF A01

This document describes the development of a new flow visualization and measurement facility that incorporates a sheet of laser light and digital image enhancement and processing techniques. A simple bench test that was used to demonstrate the feasibility of such techniques is also described. This technique offers the advantages of real time visualization of flow and the ability to freeze the flow pattern at any instant in time. In this sense, the technique plays a role similar to that of large scale direct numerical simulation of flows on supercomputers. Therefore, it will provide a better basis for code qualification than we have today. In addition, quantitative information about the flow field (e.g., the velocity vectors), both instantaneous and time-averaged, can easily be extracted from the still or video image with a high level of accuracy and in considerably shorter testing time. This is considered to be a very powerful tool for use in future computer model qualification. Because of the capabilities of the cameras in magnifying the image, this technique is far superior to previous techniques when the test geometry is very small. DOE

AN ANALYSIS OF PRESSURE DRIVEN CROSS-FLOW THROUGH A LONG SLOT CONNECTING TWO PARALLEL CHANNELS
M. A. Shadday, Jr. 1992 11 p Presented at the National Conference and Exposition on Heat Transfer, Atlanta, GA, 8-11 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC09-89SR-18035)
(DE93-040181; WSRC-MS-92-396; CONF-930830-29) Avail: CASI HC A03

Cross-flow between two parallel channels that were connected by a long narrow slot has been measured. The data was presented primarily in terms of transverse resistance coefficients. This data has been analyzed with momentum balances applied to both the axial and transverse components of the slot flow. The importance of wall friction to the slot flow and the necessity of calculating the axial component of the slot flow is demonstrated. DOE

SIMULATIONS OF DIFFUSION-REACTION EQUATIONS WITH IMPLICATIONS TO TURBULENT COMBUSTION MODELING Final Report
Sharath S. Girimaji Sep. 1993 44 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191536; NAS 1.26:191536; ICASE-93-69) Avail: CASI HC A03/MF A01

An enhanced diffusion-reaction reaction system (DRS) is proposed as a statistical model for the evolution of multiple scalars undergoing mixing and reaction in an isotropic turbulence field. The DRS model is close enough to the scalar equations in a reacting flow that other statistical models of turbulent mixing that decouple the velocity field from scalar mixing and reaction (e.g. mapping closure model, assumed-pdf models) cannot distinguish the model equations from the original equations. Numerical simulations of DRS are performed for three scalars evolving from non-premixed initial conditions. A simple one-step reversible reaction is considered. The data from the simulations are used (1) to study the effect of chemical conversion on the evolution of scalar statistics, and (2) to evaluate other models (mapping-closure model, assumed multivariate beta-pdf model). NEW RESULTS ON THE REALIZABILITY OF REYNOLDS STRESS TURBULENCE CLOSURES Final Report
Charles G. Speziale (Boston Univ., MA.), Ridha Abid (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.), and Paul A. Durbin (Stanford Univ., CA.) Oct. 1993 51 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191548; NAS 1.26:191548; ICASE-93-76) Avail: CASI HC A04/MF A01

The realizability of Reynolds stress models in homogeneous turbulence is critically assessed from a theoretical standpoint. It is proven that a well known second-order closure formulated by Shih and Lumley using the strong realizability constraints of Schumann is, in fact, not a realizable model. The problem arises from the failure to properly satisfy the necessary positive second time derivative constraint when a principal Reynolds stress vanishes - a fatal flaw that becomes apparent when the non-analytic terms in their model are made single-valued as required on physical grounds. It is furthermore shown that the centrifugal acceleration generated by rotations of the principal axes of the Reynolds stress tensor can make the second derivative singular at the most extreme limits of realizable turbulence. This previously overlooked effect appears to make it impossible to identically satisfy the strong form of realizability in any version of the present generation of second-order closures. On the other hand, models properly formulated to satisfy the weak form of realizability - wherein states of one or two component turbulence are not accessible in finite time are found to be realizable. However, unlike the simpler and more commonly used second order closures, these models can be ill-behaved near the extreme limits of realizable turbulence due to the way that higher-degree nonlinearities are often unnecessarily introduced to satisfy realizability. Illustrative computations of homogeneous shear flows are presented to demonstrate these points which can have important implications for turbulence modeling. Author

COMPUTATION OF THE SOUND GENERATED BY ISOTROPIC TURBULENCE
S. Sarkar (California Univ., San Diego.) and M. Y. Hussaini (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.) Oct. 1993 30 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-191543; ICASE-93-74; NAS 1.26:191543) Avail: CASI HC A03/MF A01

The acoustic radiation from isotropic turbulence is computed numerically. A hybrid direct numerical simulation approach which combines direct numerical simulation (DNS) of the turbulent flow with the Lighthill acoustic analogy is utilized. It is demonstrated that the hybrid DNS method is a feasible approach to the computation of sound generated by turbulent flows. The acoustic efficiency in the simulation of isotropic turbulence appears to be substantially less than that in subsonic jet experiments. The dominant frequency of the computed acoustic pressure is found to be somewhat larger than the dominant frequency of the energy-containing scales of motion. The acoustic power in the simulations is proportional to epsilon (M(sub t))(exp 5) where epsilon is the turbulent dissipation rate and M(sub t) is the turbulent Mach number. This is in agreement with the analytical result of Proudman (1952), but the constant of proportionality is smaller than the analytical result. Two different methods of computing the acoustic power from the DNS data bases yielded consistent results.

THEORETICAL RESEARCH PROGRAM TO STUDY CHEMICAL REACTIONS IN AOTV BOW SHOCK TUBES Final Technical Report, 1 Nov. 1985 - 31 Aug. 1993

Peter R. Taylor 10 Dec. 1993 10 p
(Contract NCC2-371)
(NASA-CR-194710; NAS 1.26:194710) Avail: CASI HC A02/MF A01

The main focus was the development, implementation, and calibration of methods for performing molecular electronic structure calculations to high accuracy. These various methods were then applied to a number of chemical reactions and species of interest to NASA, notably in the area of combustion chemistry. Among the development work undertaken was a collaborative effort to develop a program to efficiently predict molecular structures and vibrational frequencies using energy derivatives. Another major development effort involved the design of new atomic basis sets for use in chemical studies: these sets were considerably more accurate than those previously in use. Much effort was also devoted to calibrating methods for computing accurate molecular wave functions, including the first reliable calibrations for realistic molecules using full CI results. A wide variety of application calculations were undertaken. One area of interest was the spectroscopy and thermochemistry of small molecules, including establishing small molecule binding energies to an accuracy rivaling, or even on occasion surpassing, the experiment. Such binding energies are essential input to modeling chemical reaction processes, such as combustion. Studies of large molecules and processes important in both hydrogen and hydrocarbon combustion chemistry were also carried out. Finally, some effort was devoted to the structure and spectroscopy of small metal clusters, with applications to materials science problems. Author (revised)

MEASUREMENT OF THERMAL-HYDRAULIC PARAMETERS IN TWO-PHASE FLOW USING FLOW VISUALIZATION IMAGE ANALYSIS
T. A. Trabold Nov. 1992 65 p
(Contract DE-AC12-76SN-00052)
(DE93-006255; KAPL-4739) Avail: CASI HC A04/MF A01

Continued advances in thermal-hydraulic computer codes based on the two-fluid model formulation depend upon empirically derived constitutive relations that describe the two-phase flow field structure. A nonintrusive measurement technique, Flow Visualization Image Analysis (FVIA), has been developed to acquire some of the necessary data in test sections with visual access. The technique essentially consists of extracting quantitative information from digitized images of gas/liquid flow fields. The results of air/water experiments performed in a vertical 6.35-mm-thick duct indicate that full-field, transient, or time-averaged measurements of bubble size, shape factor, bubble number density, void fraction, and interfacial area concentration can be acquired using FVIA. Further studies are in progress to improve the associated spatial and temporal resolution, as well as to develop advanced illumination methods. NTIS

CANONICALLY COVARIANT FORMULATION OF LANDAU'S NEWTONIAN SUPERFLUID DYNAMICS
B. Carter (Centre National de la Recherche Scientifique, Meudon-Bellevue, France.) and I. M. Khalatnikov May 1993 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-221034; IHES/P/93/24) Avail: CASI HC A03

The classical Landau theory of perfect (i.e. conservative) two constituent superfluid dynamics in Newton spacetime is radically reformulated in a canonical presentation that helps to reveal symmetries and conservation properties (notably those of the thermal vorticity and helicity) that are obscured in the traditional treatment. This presentation uses a 4-dimensional terminology that is more concise and elegant than the traditional 3+1 description and that simplifies the description of transformation properties under the action of the Milne group (i.e. the nonlinear generalization of the Galilei group). F2D USERS MANUAL: A TWO-DIMENSIONAL COMPRESSIBLE GAS FLOW CODE
A. Suo-Anttila Aug. 1993 69 p Prepared for Sandia National Labs., Albuquerque, NM
(Contract DE-AC04-76DP-00789)
(DE94-000653; SAND-92-7343) Avail: CASI HC A04/MF A01

The F2D computer code is a general purpose, two-dimensional, fully compressible thermal-fluids code that models most of the phenomena found in situations of coupled fluid flow and heat transfer. The code solves momentum, continuity, gas-energy, and structure-energy equations using a predictor-corrector solution algorithm. The corrector step includes a Poisson pressure equation. The finite difference form of the equation is presented along with a description of input and output. Several example problems are included that demonstrate the applicability of the code in problems ranging from free fluid flow, shock tubes, and flow in heated porous media. DOE

MIXED FINITE ELEMENT AND FINITE VOLUME METHODS Ph.D. Thesis [METHODES D'ELEMENTS FINIS MIXTES ET VOLUMES FINIS]
Mohamed Farhloul Mar. 1991 148 p In FRENCH
(ISBN-0-315-63035-3; CTN-94-60884) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Two new mixed finite elements are presented, based on two mixed formulations of the Stokes problem in which the auxiliary variable sigma = grad u is introduced. For the two elements, it is attempted to reproduce a principal property of the finite volume method: local and consequently global conservation of mass and motion. This is done employing the Raviart-Thomas (1977) finite element as an approximation to certain unknowns of the problem. After elimination of certain variables in the algebraic equations generated by the approached problems, the same degrees of freedom for the two elements are obtained. Nevertheless, the two interpolations are different. The error estimates for the two elements are optimal. The second element has certain advantages over the first in the sense that the local conservation of motion and mass is assured by the second element, while for the first, a priori, only the mass is locally conserved. In addition, the generalization of the second element to higher degrees is immediate. The numerical results obtained (in the framework of incompressible Navier-Stokes equations) for the problems of the square cavity and flow across a step are entirely comparable with those existing in the literature. COUPLING OF SMOOTH PARTICLE HYDRODYNAMICS WITH THE FINITE ELEMENT METHOD
S. W. Attaway, M. W. Heinstein, and J. W. Swegle 1993 10 p Presented at the IMPACT-4: Structural Mechanics in Reactor Technology Conference, Berlin, Germany, 23-24 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019081; SAND-93-1806C; CONF-9308161-1) Avail: CASI HC A02/MF A01

A gridless numerical technique called smooth particle hydrodynamics (SPH) has been coupled to the transient dynamics finite element code, PRONTO. In this paper, a new weighted residual derivation for the SPH method will be presented, and the methods used to embed SPH within PRONTO will be outlined. Example SPH-PRONTO calculations will also be presented. One major difficulty associated with the Lagrangian finite element method is modeling materials with no shear strength; for example, gases, fluids and explosive bi-products. Typically these materials can be modeled for only a short time with a Lagrangian finite element code. Large distortions cause tangling of the mesh, which will eventually lead to numerical difficulties such as negative element area or 'bow tie' elements. Remeshing will allow the problem to continue for a short while, but the large distortions can prevent a complete analysis. Smooth particle hydrodynamics is a gridless Lagrangian technique. Requiring no mesh, SPH has the potential to model material fracture, large shear flows, and penetration. SPH computes the strain rate and the stress divergence based on the nearest neighbors of a particle, which are determined using an efficient particle sorting technique. Embedding the SPH method within PRONTO allows part of the problem to be modeled with quadrilateral finite elements while other parts are modeled with the gridless SPH method. SPH elements are coupled to the quadrilateral elements through a contact like algorithm. DOE

ORTHOGONALIZATION METHOD FOR DETERMINATION OF BOUNDARY LAYER RECEPTIVITY COEFFICIENTS M.S. Thesis
Michele Susanne Titcombe 1993 103 p

(ISBN-0-315-83426-9; CTN-94-60954) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The determination of coupling coefficients is part of the receptivity problem, which is the study of the generation of instability waves in boundary layers. External disturbances such as free-stream acoustic waves couple with the instability waves and hence greatly affect laminar to turbulent transition. A semi-infinite flat plate in a viscous flow with an acoustic wave serving as an excitation is considered. The effects of compressibility are taken into account. The response of the boundary layer to external excitation consists of a forced response plus an intrinsic response in the form of an eigenfunction expression whose coefficients are termed coupling coefficients. A method is described for determining coupling coefficients by comparing the superposition of the forced and intrinsic responses. The intrinsic response, in the form of an asymptotic expansion, is orthogonalized using the Gram-Schmidt process to produce an orthogonal base. The coefficients can then be extracted with the numerical solution to the flow re-expanded in terms of the original base. Author (CISTI)

A velocimeter for measuring the velocity field characteristics of a conductive fluid moving over a surface is provided. A magnet has a central axis that is aligned with a direction of fluid movement of interest such that a plurality of magnetic flux lines extend generally normal from the surface. A plurality of electrode pairs provide electrical output signals that are proportional to variations in the magnetic flux lines as the conductive fluid flows there-through in accordance with Lorentz forces. Each electrode pair is disposed symmetrically about the central axis of the magnet. The plurality of electrodes are mounted in a fixed relation with the magnet. The electrical output signals from the electrode pairs are processed and displayed as the velocity field characteristics of the fluid in the direction of interest. DTIC

Methods for fusing two computer vision methods are discussed and several example algorithms are presented to illustrate the variational method of fusing algorithms. The example algorithms solve the photo-topography problem; that is, the algorithms seek to determine planet topography given two images taken from two different locations with two different lighting conditions. The algorithms each employ a single cost function that combines the computer vision methods of shape-from-shading and stereo in different ways. The algorithms are closely coupled and take into account all the constraints of the phototopography problem. One such algorithm, the z-only algorithm, can accurately and robustly estimate the height of a surface from two given images. Results of running the algorithms on four synthetic test image sets of varying difficulty are presented. DTIC

Three liquid argon calorimeters were cooled down and operated as part of the D-Zero detector at Fermi National Accelerator laboratory. The largest vessel contains 248 metric tons of uranium and copper plates and 19 kL (5000 gal.) of liquid argon. The other two vessels are mirror images, each containing 185 metric tons of uranium and stainless steel plates and 12.1 kL (3200 gal.) of liquid argon. The cool down was accomplished by convection heat transfer between boiling liquid nitrogen filled finned heat exchangers and argon gas inside the vessels. Information regarding the general internal geometry of the calorimeters, cool down, operation, and steady state heat loads will be presented. DOE

In order to make measurements of the gluon spin or helicity distribution in the proton or the gluon spin average distribution in nuclei, both a barrel and an endcap electromagnetic calorimeter must be added to the STAR baseline detector. Information on the gluon will be obtained in inclusive direct-(gamma) + jet and jet + jet production. In order to be sensitive to the proper gluon kinematic regions, either the direct-(gamma) or the jet must be in the endcap electromagnetic calorimeter (EMC). However, the endcap EMC is not large enough to completely contain the jets, so that the barrel EMC is also needed. A conceptual design for the STAR endcap EMC is described. Constraints are imposed by the space available between the end of the time projection chamber (TPC) and the inside of the magnet pole tip iron. Severe constraints also occur near the absolute value of eta = 1, where the barrel and endcap EMC's meet. Cables from detectors inside the EMC, including those from the TPC, will exit from STAR near the absolute value of eta = 1. The constraints in this region have not yet been seriously studied since no decision on the detailed routing of these cables was available at the time this work was being done. Details of the conceptual design, analytical and finite element calculations of stresses in various structural members for the endcap EMC, and a preliminary cost estimate are included. DOE

TECHNIQUES FOR REDUCING ERROR IN THE CALORIMETRIC MEASUREMENT OF LOW WATTAGE ITEMS
W. A. Sedlacek, S. S. Hildner, K. L. Camp, and T. L. Cremers 1993 4 p Presented at the 34th Annual Meeting of the Institute of Nuclear Materials Management, Scottsdale, AZ, 18-21 Jul. 1993
(Contract W-7405-eng-36)
(DE93-018472; LA-UR-93-2638; CONF-930749-59) Avail: CASI HC A01/MF A01

The increased need for the measurement of low wattage items with production calorimeters has required the development of techniques to maximize the precision and accuracy of the calorimeter measurements. An error model for calorimetry measurements is presented. This model is used as a basis for optimizing calorimetry measurements through baseline interpolation. The method was applied to the heat measurement of over 100 items and the results compared to chemistry assay and mass spectroscopy. DOE

CALORIMETER MEASUREMENTS OF LOW WATTAGE ITEMS
T. L. Cremers, K. L. Camp, S. S. Hildner, and W. A. Sedlacek 1993 4 p Presented at the 34th Annual Meeting of the Inst. of Nuclear Materials Management, Scottsdale, AZ, 18-21 Jul. 1993
(Contract W-7405-eng-36)
(DE93-018473; LA-UR-93-2637; CONF-930749-58) Avail: CASI HC A01/MF A01

The transition of DOE facilities from production to decontamination and decommissioning has led to more measurements of waste, scrap, and other less attractive materials. The difficulty that these materials pose for segmented gamma scanning and neutron counting has increased the use of calorimetric assay for very low wattage items (less than 250 milliwatts). The authors have measured well characterized Pu-238 oxide ranging in wattage from 25 to 500 milliwatts in the calorimeters at the Los Alamos Plutonium Facility and report the error and the precision of the measurements. ROTORWASH WIND SENSOR EVALUATION Final Report
Curtis L. Meyerhoff, Robert E. Lake, and Dennis N. Gordge Aug. 1993 30 p Original contains color illustrations
(Contract DTFA01-92-Y-02017)
(AD-A268987; DOT/FAA/RD-93/10) Avail: CASI HC A03/MF A01

This project's purpose was to assess and document the ability of the Qualimetrics, Inc. model 2132 wind sensor (a cup and vane type sensor) to measure a rotor wash flow field as compared to the TSI, Inc. model 204D ion beam deflection sensor. The tests concentrated on the sensor's ability to capture dynamic characteristics of a helicopter rotor wash flow field. The project was conducted from April to November 1992 and consisted of quantitative laboratory and field testing. The laboratory testing included 9.5 hours of wind tunnel test time, subjecting each sensor to three step input tests at velocities of 20 knots, 50 knots, and 80 knots. Field test data were collected during one hour of SH-60B helicopter hover time at heights of 15 and 25 feet above ground level at distances of 35 and 70 feet from the wind sensors. Aircraft gross weights ranged between 19,600 and 20,500 pounds. All field test data were obtained in ambient wind conditions of approximately 8 knots at 40 degrees relative to the aircraft nose, -40 feet pressure altitude in an ambient temperature of 85 F. Laboratory data analysis indicates the model 2132 cup and vane sensor's time constant values were significantly higher than those of the model 204D ion beam sensor and varied relative to wind tunnel velocity settings. This indicates the model 2132 sensor's ability to accurately capture oscillations in a dynamic flow field is significantly less than the model 204D sensor. The model 2132 sensor did detect periodic or pulsating velocity magnitudes, but failed to capture significant oscillations as compared to the model 204D sensor. Comparative analysis of all field test event data indicate the model 2132 sensor only detected frequencies below 1.5 Hz and only captured an average of 46 percent of the model 204D sensor's maximum amplitude pulse values that were below 1.5 Hz. The model 2132 sensor's inability to capture many of the maximum pulse amplitudes is evidence of the sensor's limited capability to capture velocity magnitude variations in a dynamic flow field. The model 2132 cup and vane sensor's average and minimum velocities for each test event were significantly higher than the model 204D ion beam sensor's values. This is additional evidence that the model 2132 sensor is slower to respond to rapid changes in a dynamic flow field. Compared to the TSI, Inc. model 204D ion beam sensor, the Qualimetrics, Inc. model 2132 cup and vane sensor failed to measure accurately a rotorwash flow field in terms of frequency, amplitude, frequency content, and velocity magnitude and thus is not recommended for helicopter rotorwash velocity data collection. MULTIPORT SOLID-STATE IMAGER CHARACTERIZATION AT VARIABLE PIXEL RATES
G. J. Yates, K. A. Albright, and B. T. Turko (California Univ., Berkeley. Lawrence Berkeley Lab.) 1993 19 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 11-16 Jul. 1993
(Contract W-7405-eng-36)
(DE93-018366; LA-UR-93-2545; CONF-930722-18) Avail: CASI HC A03/MF A01

The imaging performance of an 8-port Full Frame Transfer Charge Coupled Device (FFT CCD) as a function of several parameters including pixel clock rate is presented. The device, model CCD-13, manufactured by English Electric Valve (EEV) is a 512 times 512 pixel array designed with four individual programmable bidirectional serial registers and eight output amplifiers permitting simultaneous readout of eight segments (128 horizontal times 256 vertical pixels) of the array. The imager was evaluated in Los Alamos National Laboratory's High-Speed Solid-State Imager Test Station at true pixel rates as high as 50 MHz for effective imager pixel rates approaching 400 MHz from multiporting. Key response characteristics measured include absolute responsivity, Charge-Transfer-Efficiency (CTE), dynamic range, resolution, signal-to-noise ratio, and electronic and optical crosstalk among the eight video channels. Preliminary test results and data obtained from the CCD-13 will be presented and the versatility/capabilities of the test station will be reviewed. DOE

DEVELOPMENT AND CHARACTERIZATION OF A TIME-, POSITION- AND ENERGY-RESOLVED X RAY DIAGNOSTIC FOR PBFA 2 TARGET EXPERIMENTS
M. S. Derzon, A. B. Filuk, J. Pantuso, R. J. Dukart, R. Olsen (EG and G Energy Measurements, Inc., Albuquerque, NM.), T. Barber (Ktech Corp., Albuquerque, NM.), and M. Bernard (Ktech Corp., Albuquerque, NM.) 1992 12 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019429; SAND-92-2754C; CONF-930722-24) Avail: CASI HC A03/MF A01

A time-, position-, and energy-resolved soft x-ray (100-500 eV) diagnostic is being developed for PBFA 2 target experiments. The diagnostic provides measurements of hydrodynamic motion and thermal gradients in light-ion fusion targets. A slit-image of the source is imprinted onto thin sheets (20 microns) of organic scintillator to create a one-dimensional image. The scintillator light is then proximity-coupled to a linear array of fiber-optics that transports the light to a streak camera that is operated without an intensifier. The streak camera output is recorded on a charge-coupled-device (CCD) camera. We are characterizing the spatial and temporal resolutions of the systems. This is done by collecting data from as many as 90 individual fibers and correcting for variations in throughput and the effects of spatial resolution to roughly 5% standard deviation in their relative throughput. Spatial resolution of these systems at the source is approximately 0.4 mm. Timing resolution is nominally 2 ns and it is limited primarily by the scintillator response and dispersion in the 50-m-long fiber array. We describe the measurement techniques and the results of the characterization. DOE

MULTISENSOR PINHOLE YAWSONDE Final Report, 1 Aug. - 30 Sep. 1990
Eugene M. Ferguson, David J. Hepner, and Wallace H. Clay Sep. 1993 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-62618-AH-80)
(AD-A271715; ARL-TR-213) Avail: CASI HC A03

The yawsonde is a device used at the U.S. Army Research Laboratory (ARL) to investigate the in-flight behavior of spinning projectiles. The standard yawsonde consists of a pair of solar cells and slits that respond to solar rays. The sun is used as an inertial reference to measure the pitching and yawing motions of the projectile. An FM telemetry package transmits the sensor data to a ground receiving station for analysis. The standard yawsonde package is housed in an M577-type artillery fuse body. The spinning motion of the projectile serves as the sampling rate for the measurements. When the spin rate is not significantly higher than the yaw rate, multiple sets of sensors must be used to effectively increase the sampling rate. The multiple-sensor pinhole yawsonde was developed for projectiles that require multiple sets of sensors in a very limited space. This pinhole yawsonde consists of a number of sensors located behind pinholes placed around the projectile's circumference. Since each pinhole makes a yaw measurement, many measurements, or samples, are taken with each projectile spin revolution. More pinhole sensors may be added to increase the measurement sampling rate. One application of this yawsonde is to aid in evaluating the performance of tactical devices and inertial systems onboard projectiles with limited space for instrumentation. DTIC

INTERNAL CAMERA CALIBRATION USING ROTATION AND GEOMETRIC SHAPES
Gideon P. Stein Feb. 1993 50 p
(Contract N00014-91-J-4038)
(AD-A272718; MIT-AI-TR-1426) Avail: CASI HC A03/MF A01

This paper describes a simple method for internal camera calibration for computer vision systems. It is intended for use with medium to wide angle camera lenses. With modification it can be used for longer focal lengths. This method is based on tracking image features through a sequence of images while the camera undergoes pure rotation. This method does not require a special calibration object. The location of the features relative to the camera or to each other need not be known. It is only required that the features can be located accurately in the image. This method can be used both for laboratory calibration and for self-calibration in autonomous robots working in unstructured environments. The method works when features can be located to single pixel accuracy, but subpixel accuracy should be used if available. DTIC

RECORDING SYSTEM USING MULTIPLEXED INPUTS TO A MULTICHANNEL RECORDER Patent
David M. Deveau, inventor (to Navy) and Victor A. Andersen, inventor (to Navy) 28 Sep. 1993 13 p Filed 7 Oct. 1991
(AD-D015971; US-Patent-5,249,085; US-Patent-Appl-SN-772186; US-Patent-Class-360-32) Avail: US Patent and Trademark Office

A system, or applique apparatus, for recording and reproducing large numbers of electrical signals on input channel limited recording devices is described. It is accomplished by time sequencing groups of pluralities of separate input signals to a plurality of recording units within a recorder, wherein each recording unit handles a separate group of input signals. The time sequence is provided by a multiplexer controller and is common to each group. The plurality of recording units after recording the signals provide them in the groups in which they were received to respective demultiplexers. A demultiplex controller that receives 2 timing signals from the multiplex controller via the recorder supplies timing signals to the plurality of demultiplexers for reconstruction of the original input signals. DIFFRACTION AND HOLOGRAPHY OF PHOTOELECTRONS AND FLUORESCENT X RAYS
C. S. Fadley Apr. 1993 19 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 12-16 Apr. 1993
(Contract DE-AC03-76SF-00098)
(DE93-019240; LBL-34374; CONF-930405-36) Avail: CASI HC A03/MF A01

Photoelectron diffraction is by now a powerful technique for studying surface structures, with special capabilities for resolving chemical and magnetic states of atoms and deriving direct structural information from both forward scattering and backscattering. Fitting experiment to theory can lead to structural accuracies in the 0.03 Angstrom range. Holographic inversions of such diffraction data also show considerable promise for deriving local three-dimensional structures around a given emitter with accuracies of 0.2-0.3 Angstrom. Resolving the photoelectron spin in some way and using circularly polarized radiation for excitation provide added dimensions for the study of magnetic systems and chiral experimental geometries. Synchrotron radiation with the highest brightness and energy

resolution, as well as variable polarization, is crucial to the full exploitation of these techniques. X-ray fluorescence holography also has promise for structural studies, but will require intense excitation sources and multichannel detection to be feasible. DOE

EXPERIMENTS IN KNOWLEDGE REFINEMENT FOR A LARGE RULE-BASED SYSTEM

Wilson A. Harvey, Jr. and Milind Tambe Aug. 1993 16 p

(Contracts DACA76-92-C-0036; F49620-92-J-0318)

(AD-A272055; CMU-CS-93-195) Avail: CASI HC A03/MF A01

Knowledge-refinement is a central problem in the field of expert systems. For rule-based systems, refinement implies the addition, deletion, and modification of rules in the system so as to improve the system's overall performance. The goal of this research effort is to understand the methodology for refining large rule-based systems, as well as to develop tools that will be useful in refining such systems. The vehicle for our investigation is SPAM, a production system (rule-based system) for the interpretation of aerial imagery. Complex and computation-intensive systems like SPAM impose some unique constraints on knowledge refinement. More specifically, the credit/blame assignment problem for locating pieces of knowledge to refine becomes difficult. Given that constraint, we approach the problem in a bottom-up fashion, i.e., begin by refining portions of SPAM's knowledge base and then attempt to understand the interactions between them. We begin by identifying gaps and/or faults in the knowledge base by comparing SPAM's intermediate output to that of an expert, then modifying the knowledge base so that the system's output more accurately matches the expert's output. While this approach leads to some improvements, it also raises some interesting issues concerning the evaluation of refined knowledge at intermediate levels and of interaction between the refinements. This paper presents our initial efforts toward addressing these issues. DTIC

MIRROR VELOCITY SAMPLING ERRORS IN A MICHELSON INTERFEROMETER Final Report, Jun. 1992 - May 1993

R. J. Combs, R. B. Knapp, and P. E. Field Sep. 1993 43 p

(AD-A273105; ERDEC-TR-106) Avail: CASI HC A03/MF A01

Mirror velocity variations in a continuous mirror drive Michelson interferometer result in erroneous interferogram sampling. The effects of systematic and random mirror fluctuations are evaluated. Four methods of evaluation provide a means to quantify the importance of mirror velocity errors in the Fourier spectrometer's performance as a spectroradiometer. The four methods are time interval signal analysis, sine wave test, optical chopper modulation, and examination of consecutive interferograms. Examination of consecutive interferograms includes the monitoring of a constant blackbody infrared radiation source as well as an interposed ammonia sample cell for wavenumber axis registration. Each method furnishes a known input to the interferometer modulation equation (i.e., 2tm = f) and permits an internal validation of the interferometer mirror velocity evaluation results. DTIC

THE ENERGY PERFORMANCE OF PROTOTYPE HOLOGRAPHIC GLAZINGS

K. Papamichael, L. Beltran, R. Furler, E. S. Lee, S. Selkowitz, and M. Rubin Feb. 1993 28 p

(Contract DE-AC03-76SF-00098)

(DE93-040451; LBL-34367) Avail: CASI HC A03/MF A01

We report on the simulation of the energy performance of prototype holographic glazings in commercial office buildings in a California climate. These prototype glazings, installed above conventional side windows, are designed to diffract the transmitted solar radiation and reflect it off the ceiling, providing adequate daylight illumination for typical office tasks up to 10m from the window. In this study, we experimentally determined a comprehensive set of solar-optical properties and characterized the contribution of the prototype holographic glazings to workplane illuminance in a scale model of a typical office space. We then used the scale model measurements to simulate the energy performance of the holographic glazings over the course of an entire year for four window orientations (North, East, South and West) for the inland Los Angeles climate, using the DOE-2.ID building energy analysis computer program. The results of our experimental analyses indicate that these prototype holographic glazings diffract only a small fraction of the incident light. The results of this study indicate that these prototype holographic glazings will not save energy in commercial office buildings. Their performance is very similar to that of clear glass, which, through side windows, cannot efficiently illuminate more than a 4-6 m depth of a building's perimeter, because the cooling penalties due to solar heat gain are greater than the electric lighting savings due to daylighting. DOE

INITIAL LABORATORY EVALUATION OF COLOR VIDEO CAMERAS, PHASE 2

P. L. Terry Jul. 1993 51 p

(Contract DE-AC04-76DP-00789)

(DE93-040201; SAND-91-2579/2) Avail: CASI HC A04/MF A01

Sandia National Laboratories has considerable experience with monochrome video cameras used in alarm assessment video systems. Most of these systems, used for perimeter protection, were designed to classify rather than to identify intruders. The monochrome cameras were selected over color cameras because they have greater sensitivity and resolution. There is a growing interest in the identification function of security video systems for both access control and insider protection. Because color camera technology is rapidly changing and because color information is useful for identification purposes, Sandia National Laboratories has established an on-going program to evaluate the newest color solid-state cameras. Phase 1 of the Sandia program resulted in the SAND91-2579/1 report titled: Initial Laboratory Evaluation of Color Video Cameras. The report briefly discusses imager chips, color cameras, and monitors, describes the camera selection, details traditional test parameters and procedures, and gives the results reached by evaluating 12 cameras. In Phase 2 of the report, six additional cameras using traditional methods were tested. In addition, all 18 cameras were tested by newly developed methods. This Phase 2 report details those newly developed test parameters and procedures, and evaluates the results. DOE

INSTANTANEOUS VELOCITY FIELD IMAGING INSTRUMENT FOR SUPERSONIC REACTING FLOWS Final Report

M. G. Allen, S. J. Davis, W. J. Kessler, H. H. Legner, K. R. McManus, P. A. Mulhall, T. E. Parker, and D. M. Sonnenfroh Cleveland, OH NASA Sep. 1993 101 p Original contains color illustrations

(Contract NAS3-26254; RTOP 324-02-00)

(NASA-CR-191162; E-8131; NAS 1.26:191162) Avail: CASI HC A06/MF A02; 2 functional color pages

The technical tasks conducted to develop and demonstrate a new gas velocity measurement technique for high enthalpy reacting flows is described. The technique is based on Doppler-shifted Planar Laser-induced Fluorescence (PLIF) imaging of the OH radical. The imaging approach permits, in principle, single-shot measurements of the 2-D distribution of a single velocity component in the measurement plane, and is thus a technique of choice for applications in high enthalpy transient flow facilities. In contrast to previous work in this area, the present program demonstrated an approach which modified the diagnostic technique to function under the constraints of practical flow conditions of engineering interest, rather than vice-versa. In order to accomplish the experimental demonstrations, the state-of-the-art in PLIF diagnostic techniques was advanced in several ways. Each of these tasks is described in detail and is intended to serve as a reference in supporting the transition of this new capability to the fielded PLIF instruments now installed at several national test facilities. Among the new results of general interest in LIF-based flow diagnostics, a detailed set of the first measurements of the collisional broadening and shifting behavior of OH (1,0) band transitions in H7-air combustion environments is included. Such measurements are critical in the design of a successful strategy for PLIF velocity imaging; they also relate to accurate concentration and temperature measurements, particularly in compressible flow regimes. Furthermore, the results shed new light on the fundamental relationship between broadening and energy transfer collisions in OH A(sup 2)Sigma(+)v(sup ') = 1. The first single-pulse, spectrally-resolved measurements of the output of common pulsed dye lasers were also produced during the course of this effort. As with the OH broadening

measurements, these data are a significant aspect of a successful velocity imaging strategy, and also have potential implications for many other LIF measurement techniques. Our results indicated the need to modify the commercially available laser cavity in order to accommodate the constraints imposed by typical SCRAMJET combustion characteristics as well as to increase the instrument's velocity dynamic range to span an intra-image range in excess of 2 km/s. The various technical efforts were brought together in a series of experiments demonstrating the applicability of the technique in a high pressure, high temperature H2-air combustion system. The resultant images were compared with 2-D flow simulations in order to determine the accuracy of the instrument. Mean velocity imaging in flows with an axis of symmetry was demonstrated with an accuracy of +/- 50 m/s out of an intra-image dynamic range of 1600 m/s, including reversed flow. A more complex configuration amenable to single-shot imaging in flows without an axis of symmetry was also demonstrated. Limitations imposed by available equipment resulted in an accuracy of about +/- 200 m/s out of 1750 m/s in these demonstrations. Minor modifications to the present configuration were suggested to improve this performance. Each technical task is described in detail, along with significance of the results for the overall imaging velocimeter configuration. This report should allow the user community to integrate this new measurement capability in their existing instrumentation platforms. Author (revised)

SOLAR IMAGING VECTOR MAGNETOGRAPH Final Technical Report, 1 Aug. 1988 - 31 Jul. 1993
Richard C. Canfield 15 Dec. 1993 7 p
(Grant NAGw-1454)
(NASA-CR-194729; NAS 1.26:194729) Avail: CASI HC A02/MF A01

This report describes an instrument which has been constructed at the University of Hawaii to make observations of the magnetic field in solar active regions. Detailed knowledge of active region magnetic structures is crucial to understanding many solar phenomena, because the magnetic field both defines the morphology of structures seen in the solar atmosphere and is the apparent energy source for solar flares. The new vector magnetograph was conceived in response to a perceived discrepancy between the capabilities of X ray imaging telescopes to be operating during the current solar maximum and those of existing magnetographs. There were no space-based magnetographs planned for this period; the existing ground-based instruments variously suffered from lack of sensitivity, poor time resolution, inadequate spatial resolution or unreliable sites. Yet the studies of flares and their relationship to the solar corona planned for the 1991-1994 maximum absolutely required high quality vector magnetic field measurements. By 'vector' measurements we mean that the observation attempts to deduce the complete strength and direction of the field at the measurement site, rather than just the line of sight component as obtained by a traditional longitudinal magnetograph. Knowledge of the vector field permits one to calculate photospheric electric currents, which might play a part in heating the corona, and to calculate energy stored in coronal magnetic fields as the result of such currents. Information about the strength and direction of magnetic fields in the solar atmosphere can be obtained in a number of ways, but quantitative data is best obtained by observing Zeeman-effect polarization in solar spectral lines. The technique requires measuring the complete state of polarization at one or more wavelengths within a magnetically sensitive line of the solar spectrum. This measurement must be done for each independent spatial point for which one wants magnetic field data. All the measurements need to be done in a time short compared to the time scale for changes of the solar features being observed. Were it possible, one would want to record all the needed data simultaneously, since temporal variation of atmospheric seeing degrades both the image and the polarization sensitivity. Since the measurements must span four dimensions, two spatial plus polarization and wavelength, we had some freedom to design the instrument to favor some dimensions over others in terms of simultaneity. Our earlier instrument, the Haleakala Stokes Polarimeter, records a range of wavelengths spanning two spectral lines in each reading, but requires two seconds to determine the polarization state and obtains spatial information only by assembling a long sequence of measurements at single locations on the sun. The new instrument sacrifices spectral detail and accuracy in favor of greatly improved imaging characteristics. The scientific goals for this instrument were to measure surface magnetic fields with enough accuracy to permit calculations of photospheric currents, but with a field of view covering an entire typical active region, high spatial resolution, and a fast enough temporal cadence for detecting flare-associated changes in magnetic structures.

(DE93-040856; UCRL-JC-113802; CONF-930405-41) Avail: CASI HC A01/MF A01

Platinum atoms near a (111) single-crystal face have been imaged using photoelectron holography. Electron angular intensity patterns were collected at equally spaced wavenumbers from 6 to 12 A(exp -1). Images of atoms near expected atomic positions are obtained from single-wavenumber analyses over the range of the data set. Positions are detected further from the emitter than we have seen previously, and symmetry assumptions are not required. We have also adopted a three dimensional means of representing the data in order to help understand the results. Twin image suppression and artifact reduction in the holographically reconstructed data are set are obtained when images at different wavenumbers are correctly phase-summed. We are assessing the capability of the technique for rendering true three-dimensional structural information for unknown systems. DOE

OTDR STRAIN GAUGE FOR SMART SKINS
S. W. Kercel Sep. 1993 67 p
(Contract DE-AC05-84OR-21400)
(DE93-041043; ORNL/TM-12383) Avail: CASI HC A04/MF A01

Optical time-domain reflectometry (OTDR) is a simple and rugged technique for measuring quantities such as strain that affect the propagation of light in an optical fiber. For engineering applications of OTDR, it is important to know the repeatable limits of its performance. The author constructed an OTDR-based, submillimeter resolution strain measurement system from off-the-shelf components. The systems repeatably resolves changes in time of flight to within +/- 2 ps. Using a 1-m, single-mode fiber as a gauge and observing the time of flight between Fresnel reflections, a repeatable sensitivity of 400 microstrains was observed. Using the same fiber to connect the legs of a 3-dB directional coupler to form a loop, a repeatable sensitivity of 200 microstrains was observed. Realizable changes to the system that should improve the repeatable sensitivity to 20 microstrains or less are discussed. DOE

FLUORESCENT MICROTHERMOGRAPHIC IMAGING
D. L. Barton 1993 32 p Presented at the 1993 International Symposium on Testing and Failure Analysis, Los Angeles, CA, 15-19 Nov. 1993
(Contract DE-AC04-76DP-00789)
(DE93-040332; SAND-93-1874C; CONF-931191-3) Avail: CASI HC A03/MF A01

In the early days of microelectronics, design rules and feature sizes were large enough that sub-micron spatial resolution was not needed. Infrared or IR thermal techniques were available that calculated the object's temperature from infrared emission. There is a fundamental spatial resolution limitation dependent on the wavelengths of light being used in the image formation process. As the integrated circuit feature sizes began to shrink toward the one micron level, the limitations imposed on IR thermal systems became more pronounced. Something else was needed to overcome this limitation. Liquid crystals have been used with great success, but they lack the temperature measurement capabilities of other techniques. The fluorescent microthermographic imaging technique (FMI) was developed to meet this need. This technique offers better than 0.01 C temperature resolution and is diffraction limited to 0.3 mircron spatial resolution. While the temperature resolution is comparable to that available on IR systems, the spatial resolution is much better. The FMI technique provides better spatial resolution by using a temperature dependent fluorescent film that emits light at 612 nm instead of the 1.5 to 12 micron range used by IR techniques. This tutorial starts with a review of blackbody radiation physics,

the process by which all heated objects emit radiation to their surroundings, in order to understand the sources of information that are available to characterize an object's surface temperature. The processes used in infrared thermal imaging are then detailed to point out the limitations of the technique but also to contrast it with the FMI process. The FMI technique is then described in detail, starting with the fluorescent film physics and ending with a series of examples of past applications of FMI. DOE

EXPERIMENTAL EVALUATION OF OXYGEN-ENRICHED AIR AND EMULSIFIED FUELS IN A SIX-CYLINDER DIESEL ENGINE
R. R. Sekar, W. W. Marr, R. L. Cole, T. J. Marciniak, and D. E. Longman (AutoResearch Labs., Inc., Chicago, IL.) Jan. 1993 356 p
(Contract W-31-109-eng-38)
(DE94-000907; ANL/ESD/TM-53) Avail: CASI HC A16/MF A03

The objectives of this investigation are to (1) determine the technical feasibility of using oxygen-enriched air to increase the efficiency of and reduce emissions from diesel engines, (2) examine the effects of water-emulsified fuel on the formation of nitrogen oxides in oxygen-enriched combustion, and (3) investigate the use of lower-grade fuels in high-speed diesel engines by emulsifying the fuel with water. These tests, completed on a Caterpillar model 3406B, six-cylinder engine are a scale-up from previous, single-cylinder-engine tests. The engine was tested with (1) intake-air oxygen levels up to 30%, (2) water content up to 20% of the fuel, (3) three fuel-injection timings, and (4) three fuel-flow rates (power levels). The Taguchi technique for experimental design was used to minimize the number of experimental points in the test matrix. Four separate test matrices were run to cover two different fuel-flow-rate strategies and two different fuels (No. 2 diesel and No. 6 diesel). A liquid-oxygen tank located outside the test cell supplied the oxygen for the tests. The only modification of the engine was installation of a pressure transducer in one cylinder. All tests were run at 1800 rpm, which corresponds to the synchronous speed of a 60-Hz generator. Test results show that oxygen enrichment results in power increases of 50% or more while significantly decreasing the levels of smoke and particulates emitted. The increase in power was accompanied by a small increase in thermal efficiency. Maximum engine power was limited by the test-cell dynamometer capacity and the capacity of the fuel-injection pump. Oxygen enrichment increases nitrogen-oxide emissions significantly. No adverse effects of oxygen enrichment on the turbocharger were observed. The engine operated successfully with No. 6 fuel, but it operated at a lower thermal efficiency and emitted more smoke and particulates than with No. 2 fuel. DOE

MSATT WORKSHOP ON INNOVATIVE INSTRUMENTATION FOR THE IN SITU STUDY OF ATMOSPHERE-SURFACE INTERACTIONS ON MARS
Bruce Fegley, Jr., ed. and Heinrich Waenke, ed. 1992 25 p Workshop held in Mainz, Germany, 8-9 Oct. 1992
(Contract NASw-4574)
(NASA-CR-194584; NAS 1.26:194584; LPI/TR-92-07-Pt-1) Avail: CASI HC A03/MF A01

Papers accepted for the Mars Surface and Atmosphere Through Time (MSATT) Workshop on Innovative Instruments for the In Situ Study of Atmosphere-Surface Interaction of Mars, 8-9 Oct. 1992 in Mainz, Germany are included. Topics covered include: a backscatter Moessbauer spectrometer (BaMS) for use on Mars; database of proposed payloads and instruments for SEI missions; determination of martian soil mineralogy and water content using the Thermal Analyzer for Planetary Soils (TAPS); in situ identification of the martian surface material and its interaction with the martian atmosphere using DTA/GC; mass spectrometer-pyrolysis experiment for atmospheric and soil sample analysis on the surface of Mars; and optical luminescence spectroscopy as a probe of the surface mineralogy of Mars. For individual titles, see N94-22431 through N94-22437.

A BACKSCATTER MOESSBAUER SPECTROMETER (BaMS) FOR USE ON MARS Abstract Only
D. G. Agresti (Alabama Univ., Birmingham.), R. V. Morris, E. L. Wills (Alabama Univ., Birmingham.), T. D. Shelfer (Alabama Univ., Birmingham.), M. M. Pimperl (Alabama Univ., Birmingham.), M.-H. Shen (Alabama Univ., Birmingham.), and T. Nguyen (Lockheed Engineering and Sciences Co., Houston, TX.) *In* Lunar and Planetary Inst., MSATT Workshop on Innovative Instrumentation for the In Situ Study of Atmosphere-Surface Interactions on Mars 1992 p 1 (For primary document see N94-22430 05-35)
Avail: CASI HC A01/MF A01

The use of Moessbauer spectroscopy for in situ analysis on the surface of Mars was proposed and the design and implementation of a backscatter Moessbauer spectrometer (BaMS) instrument suitable for planetary missions to the surfaces of Mars (MESUR), the Moon (Artemis and lunar outpost), asteroids, or other solid solar system objects is discussed. The BaMS instrument is designed to be capable of analysis of a sample for the mineralogy of its iron-bearing phases without any sample preparation. A requirement of lander missions to Mars is instrumentation for in situ mineralogical analyses. Such analyses provide data needed for primary characterization as to the type of surface materials present and by inference the processes that formed and subsequently modified them. For purposes of providing diagnostic information about naturally occurring materials, the element iron is particularly important because it is abundant and multivalent (primarily 0, +2, and +3 oxidation states). Knowledge of the oxidation state of iron and its distribution among iron-bearing mineralogies tightly constrains the types of materials present. The pivotal role of iron was already recognized in 1978 by COMPLEX, who recommended development of flight instruments that would identify mineralogy and the oxidation state of iron in planetary surface materials. The near-term U.S. strategy for the exploration of Mars is the MESUR (Mars Environmental SURvey) program, which entails emplacement of a network of small, long-lived surface landers. For the Moon, BaMS was recommended as part of a three-instrument landed payload for the Artemis missions, targeted for 1997. BaMS would prospect for ilmenite, an oxygen resource material, and provide data to assess the maturity of lunar soil. Because instrumental characteristics are low mass, low volume, and low power consumption, BaMS is suitable for implementation on even small landers and rovers, as are being envisioned in MESUR and Artemis concepts. In addition to providing highly diagnostic data, a BaMS analyzer is inherently simple and, as is highly desirable for remote operation, no sample preparation is required. Author (revised)

DATABASE OF PROPOSED PAYLOADS AND INSTRUMENTS FOR SEI MISSIONS Abstract Only
N. G. Barlow *In* Lunar and Planetary Inst., MSATT Workshop on Innovative Instrumentation for the In Situ Study of Atmosphere-Surface Interactions on Mars 1992 p 2-3 (For primary document see N94-22430 05-35)
Avail: CASI HC A01/MF A01

A database of all payloads and instruments proposed for lunar and Mars missions was compiled by the author for the Exploration Programs Office at NASA's Johnson Sapce Center. The database is an outgrowth of the document produced by C. J. Budney et al. at the Jet Propulsion Laboratory in 1991. The present database consists not only of payloads proposed for human exploratory missions of the Moon and Mars, but also experiments selected or proposed for robotic precursor missions such as Lunar Scout, Mars Observer, and MESUR. The database consists of two parts: a written payload description and a matrix that provides a breakdown of payload components. Each payload description consists of the following information: (1) the rationale for why the instrument or payload package is being proposed for operation on the Moon or Mars; (2) a description of

how the instrument works; (3) a breakdown of the payload, providing detailed information about the mass, volume, power requirements, and data rates for the constituent pieces of the experiment; (4) estimates of the power consumption and data rate; (5) how the data will be returned to Earth and distributed to the scientific community; (6) any constraints on the location or conditions under which the instrument can or cannot operate; (7) what type of crew interaction (if any) is needed; (8) how the payload is to be delivered to the lunar or martian surface (along with alternative delivery options); (9) how long the instrument or payload package will take to set up; (10) what type of maintenance needs are anticipated for the experiment; (11) stage of development for the instrument and environmental conditions under which the instrument has been tested; (12) an interface required by the instrument with the lander, a rover, an outpost, etc.; (13) information about how often the experiment will need to be resupplied with parts or consumables, if it is to be resupplied; (14) the name and affiliation of a contact person for the experiment; and (15) references where further information about the experiment can be found.

Avail: CASI HC A01/MF A01

Physical and chemical interactions between the surface and atmosphere of Mars can be expected to embody a strong cause-and-effect relationship with the minerals comprising the martian regolith. Many of the minerals in soils and sediments are probably products of chemical weathering (involving surface/atmosphere or surface/hydrosphere reactions) that could be expected to subsequently influence the sorption of atmospheric gases and water vapor. Therefore, identification of the minerals in martian surface soils and sediments is essential for understanding both past and present interactions between the Mars surface and atmosphere. Clearly, the most definitive mineral analyses would be achieved with well-preserved samples returned to Earth-based laboratories. In advance of a Mars sample return mission, however, significant progress could be made with in situ experiments that fill current voids in knowledge about the presence or abundance of key soil minerals such as clays (layered-structured silicates), zeolites, and various salts, including carbonates. TAPS is intended to answer that challenge by providing first-order identification of soil and sediment minerals.

IN SITU IDENTIFICATION OF THE MARTIAN SURFACE MATERIAL AND ITS INTERACTION WITH THE MARTIAN ATMOSPHERE USING DTA/GC Abstract Only

R. L. Mancinelli and M. R. White *In* Lunar and Planetary Inst., MSATT Workshop on Innovative Instrumentation for the In Situ Study of Atmosphere-Surface Interactions on Mars 1992 p 12-13 (For primary document see N94-22430 05-35)

Avail: CASI HC A01/MF A01

Little is known about the mineralogy of the martian surface material. Several techniques have been suggested as candidates for the in situ identification of the martian surface material. The most promising of these techniques include differential thermal analysis (DTA) coupled with gas chromatography (GC) and differential scanning calorimetry (DSC) coupled with either mass spectrometry (MS) or GC. Our studies showed that differential thermal analysis coupled with gas chromatography (DTA/GC) is a more appropriate analytical technique than DSC/MS or DSC/GC to identify the mineralogy of the martian surface material in situ. DTA/GC can be regarded as an advancement from pyrolytic GC analyses that were successfully flown on previous missions, but have supplied only limited mineralogical information.

Results from the Viking mission will form the foundation for future in-depth investigations of atmosphere-surface interactions on Mars. The two Viking landers carried impressive instrumentation to obtain and analyze soil samples: the sites were observed by cameras, and the collector head was located on a long boom and allowed the collection of large samples at various depths. A selection of grain sizes was possible and a distribution system supplied a number of experiments with soil material. Despite stationary vehicles, a wide sampling field was reachable. The GCMS system, responsible for atmospheric as well as surface soil analysis, worked well on both landers. Atmospheric measurements resulted in the determination of the abundance of noble gases as well as of other molecular species. Isotopic composition measurements included the important ratios of C-13/C-12, N-15/N-14, and Ar-36/Ar-40. To verify these past results and to advance detailed studies of noble gas isotope ratios and minor constituents, better instrument sensitivities, higher precision, and lower background contributions are required in future Mars missions. Soil analysis during the Viking mission concentrated on organic material. Heating cycles were performed to 500 C and only water and carbon dioxide were identified. Higher pyrolysis temperatures are of primary importance to advance our understanding of the mineralogy and gas loading of surface material and atmospheric exchange.

Two intense microwave spectra lines exist in the martian atmosphere that allow unique sounding capabilities: water vapor at 183 GHz and the (2-1) rotational line of CO at 230 GHz. Microwave spectra line sounding is a well-developed technique for the Earth's atmosphere for sounding from above from spacecraft and airplanes, and from below from fixed surface sites. Two simple instruments for temperature sounding on Mars (the CO line) and water vapor measurements are described. The surface sounder proposed for the MESUR sites is designed to study the boundary layer water vapor distribution and the temperature/pressure profiles with vertical resolution of 0.25 km up to 1 km with reduced resolution above approaching a scale height. The water channel will be sensitive to a few tenths of a micrometer of water and the temperature profile will be retrieved to an accuracy between 1 and 2 K. The latter is routinely done on the Earth using oxygen lines near 60 GHz. The measurements are done with a single-channel heterodyne receiver looking into a 10-cm mirror that is canned through a range of elevation angles plus a target load. The frequency of the receiver is sweep across the water and CO lines generating the two spectra at about 1-hr intervals throughout the mission. The mass and power for the proposed instrument are 2 kg and 5-8 W continuously. The measurements are completely immune to the atmospheric dust and ice particle loads. It was felt that these measurements are the ultimate ones

to properly study the martian boundary layer from the surface to a few kilometers. Sounding from above requires an orbiting spacecraft with multichannel microwave spectrometers such as the instrument proposed for MO by a subset of the authors, a putative MESUR orbiter, and a proposed Discovery mission called MOES. Such an instrument can be built with less than 10 kg and use less than 15 W. The obvious advantage of this approach is that the entire atmosphere can be sounded for temperature and water vapor in a few hours with somewhat better than a scale height resolution. If a bigger mirror is used (greater than 30 cm) limb sounding geometry can be employed and half scale height resolution achieved to altitudes up to at least 60 km. Again, the measurements are immune to dust and ice loads. Water vapor sensitivity of 0.1 micrometer can be achieved (even with a nadir instrument) and temperature profiles retrieved to an accuracy of better than 2 K from the surface to about 60 km. Winds can be measured from the doppler shifts of CO lines in the limb sounding mode. Author (revised)

OPTICAL LUMINESCENCE SPECTROSCOPY AS A PROBE OF THE SURFACE MINERALOGY OF MARS Abstract Only

A. H. Treiman *In* Lunar and Planetary Inst., MSATT Workshop on Innovative Instrumentation for the In Situ Study of Atmosphere-Surface Interactions on Mars 1992 p 17 (For primary document see N94-22430 05-35)

Avail: CASI HC A01/MF A01

Optical luminescence (OpL) spectroscopy is an attractive use of a visible-near-IR spectrometer on a Mars lander because mineral products of atmosphere-surface interactions on Mars will probably have characteristic OpL spectra. Optical luminescence spectra would be taken at night, when a spectrometer might otherwise sit idle. Also needed would be a source of exciting radiation, which could be shared with other experiments. Optical luminescence is emission of nonthermal optical photons (near-UV through near-IR) as a response to energy input. On absorption of energy, an atom (or ion) will enter an excited state. The favored decay of many such excited states involving valence-band electrons is emission of an optical photon. Optical luminescence spectra can be useful in determining mineralogy and mineral composition. Optical luminescence in crystals can arise from essential elements (or ions), trace-element substituents (activators), or defects. Common activators in salts of alkali and alkaline earth elements include Mn(2+)(VI), other transition metals, the rare earths, and the actinides. Trace substituents of other species can enhance or quench OpL (e.g., Pb(2+) vs. Fe(3+)). Optical luminescence can also arise from defects in crystal structures, including those caused by radiation and shock. Author (revised)

(AD-D015928; US-Patent-5,206,867; US-Patent-Appl-SN-829145; US-Patent-Class-372-20) Avail: US Patent and Trademark Office

A flashpumped, tunable, two-micron, solid state laser is disclosed in which laser spiking is suppressed. The solid state laser comprises: a laser cavity defined by a first reflective element and an output coupler reflective element to form a reflective path there between; a laser crystal disposed in the laser cavity, the laser crystal having a host material doped with preselected activator ions sufficient to produce a pulse or laser emission at a desired laser transition wavelength in a range between about 1.9 microns and about 2.1 microns when the crystal is optically excited to produce the laser emission; a pulsed flashlamp for optically exciting the laser crystal to produce a pulse of laser emission at the desired laser transition wavelength; a tuner disposed in the laser cavity between the laser crystal and one of the reflective elements for tuning the laser emission to the desired laser transition wavelength in the range of wavelengths between about 1.9 microns and about 2.1 microns; optical plates oriented at Brewster's angle in the reflective path for suppressing oscillation of undesired wavelengths within the laser cavity; and a nonlinear crystal disposed in the reflective path to enable the laser to emit through the output coupler reflective element a smooth, long pulse of laser emission without spiking at the desired laser transition wavelength. The Los Alamos compact Advanced FEL has lased at 4.7 and 5.2 micron with a 1-cm period wiggler and a high-brightness electron beam at 16.8 and 15.8 MeV, respectively. The measured electron beam normalized emittance is 1.7 pi mm mrad at a peak current of 100 A, corresponding to a beam brightness greater than 2 x 10(exp 12) A/sq m rad(exp 2). Initial results indicate that the AFEL small signal gain is approximately 8% at 0.3 nC (30 A peak). The maximum output energy is 7 mJ over a 2-micro-s macropulse. The AFEL performance can be significantly enhanced by improvements in the rf and drive laser stability. DOE

DESIGN ASPECTS AND PARAMETRIC CHARACTERISATION OF A NEUTRAL RARE GAS LASER
Kenneth J. Grant May 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271100; ERL-0703-GD; DODA-008-148) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A neutral rare gas laser has been built and used to produce continuous wave output at several wavelengths in the mid-infrared region. The laser design is described and results are presented of a parametric study of its operating characteristics. Mixtures of He-Ar, He-Kr, and He-Xe were used. The output power at each wavelength was monitored as a function of the discharge parameters to determine the optimum working regimes. With support from the Air Force Office of Scientific Research, we have developed a hydrogen maser that operates near 0.5 K using a high-cooling-power 3 He refrigerator. We have used this cryogenic hydrogen maser to study low temperature atomic hydrogen spin-exchange collisions and hydrogen-helium interactions and to investigate the performance of cryogenic hydrogen masers as possibly improved frequency standards. FIRST RESULTS ON InGaAsP SEPARATE CONFINEMENT HETEROSTRUCTURE DIODE LASERS Interim Technical Report, 15 Mar. - 9 Sep. 1993
M. Razeghi 9 Sep. 1993 31 p
(Contract DAAH04-93-G-0044)
(AD-A270849; ARO-31108.2-PH) Avail: CASI HC A03/MF A01

The first attempts of fabrication of InGaAsP/GaAs SCH-QW laser structures allowed to obtain laser diodes with threshold current densities as low as 47O A/sq cm and differential efficiencies as high as 0.7 W/A. Long-cavity (L approx. 1mm) laser diodes have low series resistances of 0.1-0.4 ohms. These diodes are suitable for testing of the properties of the Al-free material in continuous wave regime. At the same time, it is evident that further optimization of structure parameters is necessary to reach the ultimate performance expected for InGaAsP SCH QW lasers. DTIC

TUNABLE LASER FREQUENCY STABILIZING SYSTEM Patent
David F. Hudson, inventor (to Navy) 29 Jun. 1993 6 p Filed 27 May 1992
(AD-D015904; US-Patent-5,224,110; US-Patent-Appl-SN-888996; US-Patent-Class-372-32) Avail: US Patent and Trademark Office

Laser emissions are stabilized at a plurality of frequencies by passage through an absorbing medium pumped by light, merged therewith, to an excited energy state corresponding to pumping light frequencies. Error signals are generated in response to detection of intensity of radiation exiting the absorbing medium which deviates from that of the laser emissions at the stabilizing frequencies to correctively adjust resonant cavity length of the laser generator being frequency stabilized. This invention is a laser system and method for producing a laser emission at a wavelength of substantially 2.8 microns and having a quantum efficiency of at least unity and a slope efficiency of about 36%. In a preferred embodiment of the invention, the laser system comprises a laser cavity defined by first and second reflective elements with one of the reflective elements operating as an output coupler; a crystal disposed in the laser cavity and having a GSGG host material doped with a preselected percent concentration of erbium, the GSGG host material and preselected percent concentration of erbium being selected so as to provide a quantum efficiency of at least unity by the 4I13/2 + 4I13/2 right arrow 4I9/2 + 4I15/2 upconversion process and a slope efficiency of about 36% when the crystal is resonantly pumped; and a resonant pump laser for directly pumping the 4I11/2 upper laser state of the erbium with a pump beam to cause the crystal to produce a laser emission corresponding to the 4I11/2 right arrow 4I13/2 laser transition having a wavelength of substantially 2.8 microns. APPLICATIONS AND SOURCE DEVELOPMENT FOR HIGH-REPETITION RATE X RAY LASERS
D. C. Eder, P. Amendt, and P. R. Bolton et al 30 Jul. 1993 9 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract W-7405-eng-48)
(DE93-019547; UCRL-JC-112493; CONF-930722-30) Avail: CASI HC A02/MF A01

Many applications in material science, chemistry, and atomic physics require an x-ray source that has a repetition rate of 1 Hz to a few kHz. In these fields, a very wide range of photon energies is of interest. One application is time-resolved surface photoelectron spectroscopy and microscopy where low energy (less than 1 micro-J) pulses are required to avoid space charge effects but high-repetition rates (approximately 1 kHz) provide the high average power which is needed to obtain the desired resolution. In pump-probe experiments, it is desirable to have the repetition rate of the x-ray source be comparable to the repetition rate of the corresponding IR, optical, or UV laser. The authors show that the very high-repetition rate of synchrotrons (1-1000 MHz) results in an inefficient use of x rays for these types of experiments and that a kHz repetition rate x-ray laser would be an excellent source for many experiments. For some applications, a slower repetition rate of order 1 Hz is adequate provided the energy per pulse is larger (approximately 1 mJ). For example, in photoelectron spectroscopy of free clusters, an x-ray laser can provide the required large number of nearly mono-energetic photons during the short time the clusters can be probed in each formation cycle. In the context of source development, the authors discuss conventional collisional x-ray laser schemes with mJ output pulses that can operate at Hz repetition rates using a high average power driving laser. The near term prospects for high-repetition rate x-ray lasing for photon energies below 100 eV are very good with higher energy capabilities expected in the future. In addition, prospects of table-top size x-ray lasers with kHz repetition rates are presented. DOE

MEASUREMENT AND CORRECTION OF MAGNETIC FIELDS IN PULSED SLOTTED-TUBE MICROWIGGLERS
C. M. Fortgang and R. W. Warren 1993 10 p Presented at the 15th International Free Electron Laser Conference, The Hague, Netherlands, 23-27 Aug. 1993
(Contract W-7405-eng-36)
(DE93-040100; LA-UR-93-2924; CONF-930855-2) Avail: CASI HC A02/MF A01

Pulsed electromagnetic microwigglers are capable of creating stronger fields with shorter periods than conventional wigglers. Wiggler field parameters of 1 Tesla and 5-mm period are achieved by passing approximately 25 kA down a slotted 3 mm outer diameter copper tube. The taut-wire technique is used to measure the wiggler magnetic field in a small aperture (approximately 1.7 mm) with the required spatial (0.1 mm)

and temporal (approximately 5 microsecond) resolution. The absence of midplane symmetry, in contrast to permanent magnet wigglers, causes unique problems in our microwigglers. We have measured strong dipole (bending) and quadrupole (defocusing) field errors with both dc and time-dependent parts. The effects on the magnetic field of current redistribution caused by heating in the copper tube has been measured. We have identified causes for the various field errors and their sensitivities to fabrication tolerances. Improvements we have made towards meeting the required tolerances and our field-correction technique are discussed. DOE

(Contract W-7405-eng-36)
(DE93-040141; LA-UR-93-3101; CONF-930855-1) Avail: CASI HC A03/MF A01

The AFEL accelerator has produced beams of greater than 2 x 10(exp 12) A/m(exp 2) at 1 nC (brightness = 2*I/(var epsilon)(exp 2), with I greater than 100 A and (var epsilon) of than 2(pi) mm-mrad normalized ms emittance). The 1300 MHz standing-wave accelerator uses on-axis coupling cells. The electron source is a photoinjector with a CsK2Sb photocathode. The photoinjector is an integral part of a single 11-cell accelerator structure. The accelerator operates between 12 and 18 MeV. The beam emittance growth in the accelerator is minimized by using a photoinjector, a focusing solenoid to correct the emittance growth due to space charge, and a special design of the coupling slots between accelerator cavities to minimize quadrupole effects. This paper describes the experimental results and compares those results with PARMELA simulation. The simulation code PARMELA was modified for this effort. This modified version uses SUPERFISH files for the accelerator cavity fields, MAFIA files for the fields due to the coupling slots in the accelerator cells, and POISSON files for the solenoid field in the gun region. PHOTOPUMPED X RAY LASER RESEARCH ON SATURN
T. J. Nash, R. B. Spielman, M. Vargas, and L. Ruggles 1993 11 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019430; SAND-93-1639C; CONF-930722-25) Avail: CASI HC A03/MF A01

Using Saturn as a driver, we are pursuing both photoresonantly pumped and photoionization/recombination lasers. Our lasing targets are gas cells with thin windows that are pumped by a z pinch 2 cm away radiating 10 TW. In both schemes the lasant and gas fill is neon. We will present evidence for inversion in the sodium/neon photoresonant scheme, but we have yet to detect the lasing transition itself. To increase our chances of measuring this line we have introduced potassium into a sodium z-pinch and have eliminated oxygen from the gas cell windows. We have measured the spatial dependence of ionization balance across the gas cell, and this measurement is consistent with propagation of a shock front across the gas cell target. We have measured the Li-like neon 5f-3d transition to increase more rapidly with fill pressure than all other measured lines. Based on this result we have performed experiments emphasizing the photoionization/recombination laser scheme that use a flat-field grazing incidence spectrometer to provide good spatial resolution of the 4f-3d, 4d-3p, and 5f-3d lines of Li-like neon. We have attempted a gain length measurement by imaging parallel to a baffle that varies the length of the target illuminated. DOE

COHERENT LIDAR DESIGN AND PERFORMANCE VERIFICATION Annual Report, 1 Dec. 1992 - 1 Dec. 1993
Rod Frehlich 1993 97 p
(Grant NAG8-253)
(NASA-CR-193813; NAS 1.26:193813) Avail: CASI HC A05/MF A02

The verification of LAWS beam alignment in space can be achieved by a measurement of heterodyne efficiency using the surface return. The crucial element is a direct detection signal that can be identified for each surface return. This should be satisfied for LAWS but will not be satisfied for descoped LAWS. The performance of algorithms for velocity estimation can be described with two basic parameters: the number of coherently detected photo-electrons per estimate and the number of independent signal samples per estimate. The average error of spectral domain velocity estimation algorithms are bounded by a new periodogram Cramer-Rao Bound. Comparison of the periodogram CRB with the exact CRB indicates a factor of two improvement in velocity accuracy is possible using non-spectral domain estimators. This improvement has been demonstrated with a maximum-likelihood estimator. The comparison of velocity estimation algorithms for 2 and 10 micron coherent lidar was performed by assuming all the system design parameters are fixed and the signal statistics are dominated by a 1 m/s rms wind fluctuation over the range gate. The beam alignment requirements for 2 micron are much more severe than for a 10 micron lidar. The effects of the random backscattered field on estimating the alignment error is a major problem for space based lidar operation, especially if the heterodyne efficiency cannot be estimated. For LAWS, the biggest science payoff would result from a short transmitted pulse, on the order of 0.5 microseconds instead of 3 microseconds. The numerically errors for simulation of laser propagation in the atmosphere have been determined as a joint project with the University of California, San Diego. Useful scaling laws were obtained for Kolmogorov atmospheric refractive turbulence and an atmospheric refractive turbulence characterized with an inner scale. This permits verification of the simulation procedure which is essential for the evaluation of the effects of refractive turbulence on coherent Doppler lidar systems. The analysis of 2 micron Doppler lidar data from Coherent Technologies, Inc. (CTI) has demonstrated many of the advantages of doppler lidar measurements of boundary layer winds. The effects of wind shear and wind turbulence over the pulse volume are probably the dominant source of the reduced performance. The effects of wind shear and wind turbulence on the statistical description of doppler lidar data has been derived and calculated. Derived from text

LASER PROPAGATION IN UNDERDENSE PLASMAS: SCALING ARGUMENTS
J. C. Garrison May 1993 23 p
(Contract W-7405-eng-48)
(DE93-040439; UCRL-ID-114297) Avail: CASI HC A03/MF A01

The propagation of an intense laser beam in the underdense plasma is modelled by treating the plasma as a relativistic, zero temperature, charged fluid. For paraxial propagation and a sufficiently underdense plasma (omega p/(omega) much less than 1), a multiple-scales technique is used to expand the exact equations in powers of the small parameter theta equivalent to omega p/(omega). The zeroth order equations are used in a critical examination of previous work on this problem, and to derive a scaling law for the threshold power required for cavitation. DOE

ANALYSIS AND DESIGN OF WEIGHT BALANCING SYSTEM FOR LASER VELOCIMETRY TRAVERSE Final Report, Jun. 1989 - Sep. 1993
Hsue-Fu Lee Sep. 1993 23 p
(AD-A271171; WL-TM-93-307) Avail: CASI HC A03/MF A01

This technical memorandum describes the process of designing the weight balancing system which is an in-house effort to extend the lifting capability of the vertical axis of the Anomatic II system. The Anomatic II system is a programmable three-dimensional positioning controller used as

a laser velocimetry traverse. The Anomatic II system is the prime mover and the weight balancing system is an add-on follower that derives its motion and speed in response to the Anomatic II system. The weight balancing system consists primarily of a pneumatic cylinder-steel cable mechanism which proves to be effective in lifting excessive weight, economic in construction and simple to operate. DTIC

DEVELOPMENT OF A LIDAR FOR INTEGRATION WITH THE NAVAL POSTGRADUATE SCHOOL INFRARED SEARCH AND TARGET DESIGNATION (NPS-IRSTD) SYSTEM M.S. Thesis
Murray M. Regush Jun. 1993 103 p
(AD-A271847) Avail: CASI HC A06/MF A02

A lidar was designed and manufactured at the Naval Postgraduate School, Monterey, CA, to provide range information to atmospheric features, such as clouds. It is further planned to integrate the lidar with the NPS-IRSTD system at some future date. The NPS-IRSTD uses two vertical linear focal plane arrays for target detection and target direction can be determined very accurately but the system does not provide any useful range information. The lidar was proposed as the solution for this shortcoming. The lidar used a frequency-doubled Nd:YAG laser which had an energy output of 2 millijoules. The laser beam was expanded to 17.75 inches using a Dall-Kirkham telescope to operate within laser safety limitations. The theoretical analysis of the 'Klett' method for the inversion of lidar returns was derived and a MATLAB program was written to demonstrate the process. A daytime and nighttime maximum range equation for the lidar was developed. The considerations for integrating the lidar with the NPS-IRSTD were listed and a solution was proposed to obtain the mean extinction coefficient along the path in the infrared spectrum using the lidar inversion extinction coefficient profile at 532 nanometers. LONG-RANGE LASER IMAGING Final Report, Jan. - Jul. 1993
Joseph C. Marron and Richard G. Paxman 30 Sep. 1993 63 p
(Contract DLA900-88-D-0392)
(AD-A273020; ERIM-246830-9-F) Avail: CASI HC A04/MF A01

This report summarizes a research program in which we evaluated the use of a Long-Range Laser Imaging (LRLI) system to perform the imaging tasks associated with laser target designation. The motivation for LRLI is to improve crew and aircraft survivability by increasing the standoff range and reducing the required time interval for air-based laser target designation. In this program, we analyzed the capabilities of LRLI systems. We considered the signal level and its impact on sensor field-of-view. This analysis includes laser selection, atmospheric transmission, target reflectivity, and optical system characteristics. It is shown that the laser signal level ultimately limits the number of target pixels. It is also shown that a pulsed system is required for background rejection. The impact of optical turbulence on system performance is also discussed. We evaluated the achievable resolution and considered the use of adaptive optics. It is shown, however, that severe anisoplanatism limits the utility of adaptive optics. We conclude that the most promising sensor design is based on conventional imaging and recommendations for proof-of-concept experiments are given. DTIC

COMPACT LIGHTWEIGHT CO2 LASER FOR SDIO APPLICATION Final Report, 1 Jul. 1990 - 30 Jun. 1992
Stephen Fulghum and Jonah Jacob 15 Nov. 1993 50 p
(Contract N00014-90-C-0162)
(AD-A273010; SRL-12-F-1993) Avail: CASI HC A03/MF A01

SRL has combined two all-solid-state pulsed power generators based on SCR-commutated nonlinear magnetic pulse compressors with low-pressure, conduction-cooled, CO2 laser cavities in a program to produce high repetition rate laser systems without the weight penalty of flow loop cooling. The first CO2 system used a transverse discharge, rectangular slab geometry, laser amplifier matched to the 10 Hz, SRL COLD-I solid-state pulser. Visible interferometric probes of the slab geometry laser medium showed the characteristic cylindrical wavefront error expected of a uniformly heated slab cooled at its walls. Conduction cooling of the 2.4 cm slab was sufficient to dissipate the thermal energy deposited by a single pulse dissipated to below the measurement level within 100 ms (10 Hz). The second CO2 system used a longitudinal discharge, cylindrical geometry, laser amplifier combined with the new SSLAM-VIII pulser which produces 72 KV, 30 J pulses at up to 5 KHz. The longitudinal laser output power typically peaked at 50 Hz since the heat load from higher repetition rates could not be dissipated sufficiently rapidly from the 4 cm diameter discharge. Due to an impedance mismatch the maximum single pulse energy in steady state operation was 350 mJ (18 W average power). A circuit to provide proper matching has been designed but has not yet been implemented. DTIC

GENERATION OF INTENSE ULTRASHORT X RAY PULSES
D. C. Eder, R. A. London, M. D. Rosen, and G. L. Strobel (Georgia Univ., Macon.) Aug. 1993 11 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract W-7405-eng-48)
(DE93-019607; UCRL-JC-112492; CONF-930722-29) Avail: CASI HC A03/MF A01

Modeling of x-ray emission from targets heated by an ultrashort-pulse high-intensity optical laser is discussed. One application, using the emitted x rays, is pumping inner-shell photo-ionized x-ray lasers. Short wavelength lasing (lambda less than or equal to 15 Angstrom) requires fast rise-time 1-3 KeV x rays to ionize inner K-shell electrons. It was shown that structured targets, consisting of grooves on a solid material or a composite of clusters, have high absorption. Grooved targets are modeled as an ensemble of exploding foils finding that the rise time of x rays is rapid enough for pumping inner-shell x-ray lasers. It is shown that simple atomic models can overestimate the energy in x-ray emission bands. High-Z materials are found to have the highest conversion efficiency but mid-Z materials can be used to provide a band of emission at a particular energy. It is shown that the pondermotive inhibition of expansion has only a small effect on the x-ray emission. The emission of a Au plasma is found to be appropriate for pumping inner-shell lasing at 14.6 Angstrom in Ne. The required optical laser intensity is of order 10(exp 17) W/cm(sup 2) using a 100 fsec FWHM duration pulse. To produce a laser with a gain-length product of order 10 requires 5-15 J of optical energy. DOE

A THEORY FOR OPTICAL WAVELENGTH CONTROL IN SHORT PULSE

FREE ELECTRON LASER OSCILLATORS M.S. Thesis
Wade F. Wilkenson Jun. 1993 110 p
(AD-A271706) Avail: CASI HC A06/MF A02

The future safety of the U.S. Navy warship depends on the development of a directed energy self-defense system to keep pace with the ever-improving technology of anti-ship missiles. Two candidates are reviewed. The free electron laser (FEL) has the most advantages, but a chemical laser proposed by TRW is ready for installation on existing ships. Initial testing of issues related to directed energy use at sea can be conducted with the chemical laser. When the technology of the FEL matures, it can replace the chemical laser to provide the best possible defense in the shortest period of time. Continuous tunability is a key advantage of the FEL over the conventional laser. But since the output wavelength is dependent on electron energy, it is subject to random fluctuations originating from the beam source. At the Stanford University Superconducting (SCA) Free Electron Laser (FEL) Facility, the effects are minimized through negative feedback by changing the input electron energy proportional to the observed wavelength drift. The process is simulated by modifying a short pulse FEL numerical program to allow the resonant wavelength to vary over many passes. The physical effects behind optical wavelength control are explained. A theory for the preferential nature of the FEL to follow the resonant wavelength from longer to shorter wavelengths is presented. Finally, the response of the FEL to a rapidly changing resonant wavelength is displayed as a transfer function for the system. DTIC

EFFECTS OF STIMULATED RAMAN SCATTERING ON LIGHT BEAM PROPERTIES DURING HIGH-POWER LASER BEAM LONG-PATH PROPAGATION
Lian Chien, Zhan Shui, Xiao-Min Zhang, Xiao-Feng Wei, and Xiao-Dong Yuan 3 Nov. 1993 19 p Transl. into ENGLISH from Qiongjiguang Yu Lizishu (China), v. 4, no. 2, May 1992 p 277-283
(AD-A273109; FASTC-ID(RS)T-0100-93) Avail: CASI HC A03/MF A01

Beginning from the third-order nonlinear polarization from the stimulation and induction of matter based on the semiclassical theory of stimulated Raman scattering (SRS), a theoretical model of coupling between the phase of a pump (transmission) laser beam and the phase of the Stokes beam intensity is established for the case of stimulated Raman scattering during long-path propagation of a high-power laser. The model clearly explains how the SRS effect influences the beam properties of the pump laser, including the physical regime and effective factors of time-domain properties and space-domain properties (light beam quality). The theoretical analysis is in fairly satisfactory agreement with the experimental results. In the experiments, measurements of time-domain properties were taken of the pump laser beam and the Stokes beam after transmission in a situation with various conversion efficiencies eta(sub s). As shown by the results, under conditions of low-conversion efficiencies, basically the time-domain properties of the pump laser beam are not affected by the SRS effect. But when the conversion efficiency eta(sub s) is greater than five percent, the pulse duration of the pump laser beam is gradually reduced as eta(sub s) is increased. DTIC

An extensive series of experiments has been conducted on the Nova laser to measure hydrodynamic instabilities in planar foils accelerated by x-ray ablation. Single mode experiments allow a measurement of the fundamental growth rates from the linear well into the nonlinear regime. Two-mode foils allow a first direct observation of mode coupling. Surface-finish experiments allow a measurement of the evolution of a broad spectrum of random initial modes. DOE

We report on the design details of the first ultraviolet (UV) free-electron laser (FEL) oscillator driven by low-energy electrons from a radio-frequency linear accelerator. In our experiment we used a high-current, high brightness electron beam in combination with a wiggler of novel design to produce an FEL that lased at wavelengths from 369-380 nm using 45.9-45.2 MeV electrons. In addition we performed a proof-of principle experiment that demonstrated the first ever photolithography on a photoresist-coated silicon wafer using an FEL light source. DOE

DETERMINING THE 3-D STRUCTURE AND MOTION OF OBJECTS USING A SCANNING LASER RANGE SENSOR Progress Report, 1 Sep. - 15 Dec. 1993
N. Nandhakumar and Philip W. Smith Dec. 1993 12 p
(Grant NGT-51055)
(NASA-CR-194745; NAS 1.26:194745; UVA/528476/EE94/101) Avail: CASI HC A03/MF A01

In order for the EVAHR robot to autonomously track and grasp objects, its vision system must be able to determine the 3-D structure and motion of an object from a sequence of sensory images. This task is accomplished by the use of a laser radar range sensor which provides dense range maps of the scene. Unfortunately, the currently available laser radar range cameras use a sequential scanning approach which complicates image analysis. Although many algorithms have been developed for recognizing objects from range images, none are suited for use with single beam, scanning, time-of-flight sensors because all previous algorithms assume instantaneous acquisition of the entire image. This assumption is invalid since the EVAHR robot is equipped with a sequential scanning laser range sensor. If an object is moving while being imaged by the device, the apparent structure of the object can be significantly distorted due to the significant non-zero delay time between sampling each image pixel. If an estimate of the motion of the object can be determined, this distortion can be eliminated; but, this leads to the motion-structure paradox - most existing algorithms for 3-D motion estimation use the structure of objects to parameterize their motions. The goal of this research is to design a rigid-body motion recovery technique which overcomes this limitation. The method being developed is an iterative, linear, feature-based approach which uses the non-zero image acquisition time constraint to accurately recover the motion parameters from the distorted structure of the 3-D range maps. Once the motion parameters are determined, the structural distortion in the range images is corrected. Author (revised)

(DE93-019160; UCRL-JC-114023; CONF-9301119-2) Avail: CASI HC A03

The motivation for the present ionization calculations is to test the reliability of a recent study of H2(+) photodissociation which employed such a two electronic state model and neglected any competition with ionization. The photodissociation calculations indicate that in intense short pulsed laser fields appreciable populations of stable vibrational states can survive the pulse. This survival effect can be attributed to the trapping of portions of the initial vibrational wavepacket in transient laser-induced

potential wells at intermediate R approximately 3-4 au distances. Since the calculated ionization rates exhibit a marked decrease at short R, they already lend some credence to the vibrational trapping effect. Having accurate R-dependent rates enables us to estimate the competitive influence of the ionization on the stabilized population, and may ultimately allow us to predict the contribution of the Coulomb 'explosion' channel to observed proton kinetic energy distributions. In this paper we will demonstrate the effectiveness of the two-state length gauge model in interpreting the ionization rates that we extract from the numerically exact solutions of the time-dependent Schroedinger equation. A more elaborate presentation of the theory and the results for the full range of distances and wavelengths will be presented elsewhere. DOE

STABILITY ANALYSIS OF UNSTEADY ABLATION FRONTS
R. Betti, R. L. McCrory, and C. P. Verdon Aug. 1993 10 p
(Contract DE-FC03-92SF-19460)
(DE93-019689; DOE/DP-40200-265) Avail: CASI HC A02/MF A01

The linear stability analysis of unsteady ablation fronts is carried out for a semi-infinite uniform medium. For a laser accelerated target, it is shown that a properly selected modulation of the laser intensity can lead to the dynamic stabilization or growth-rate reduction of a large portion of the unstable spectrum. The theory is in qualitative agreement with the numerical results obtained by using the two-dimensional hydrodynamic code ORCHID. DOE

High-power copper vapor lasers (CVL's) have been under development at Lawrence Livermore National Laboratory (LLNL) for more than 15 years in support of the DOE's Program in Laser Isotope Separation. The technology is now quite mature having met many of its goals in system architecture, power, reliability, and maintainability. Over the past several years we have begun an effort to utilize this technology in other industrial applications, such as metals processing, and have found a number of unique processes. In this paper we describe briefly the general characteristics of the CVL, our recent progress in developing the laser as an industrial tool, and our progress in using the laser in precision drilling and cutting. (DE93-019623; UCRL-JC-112742; CONF-930159-55) Avail: CASI HC A03

Spectral broadening of single-frequency laser pulses by optical cross-phase modulation (XPM) with chaotic laser pulses in birefringent single-mode optical fibers is investigated numerically and results are compared with experiments. By this process we have generated laser pulses of variable bandwidth (1-25 A) at the fundamental wavelength (1053 nm) for amplification in high power solid-state Nd:glass lasers used for inertial confinement fusion research. Simulations indicate that a temporally smooth XPM pulse can be generated with intensity fluctuations of less than 10% and spectral width greater than 50 A using a short length (approximately 5 m) of special low dispersion and low birefringence fiber, e.g. D = 10 ps/nm-km (normal dispersion) and Delta-n = 2 x 10(exp -5). Readily available fibers of similar length, with parameters of D = 40 ps/nm-km and Delta-n = 6 x 10(exp -5), can give spectral widths exceeding 25 A, but the noise will range from 25 to 60%. Broadband laser pulses generated by XPM are now routinely used at Lawrence Livermore National Laboratory for active smoothing of the laser irradiance on targets by the technique of smoothing by spectral dispersion. DOE

SHATTERING THE MYTH OF THE RESONANTLY PHOTO-PUMPED NEON-LIKE TITANIUM LASER
J. Nilsen, B. J. MacGowan, L. B. DaSilva, J. C. Moreno, and J. A. Koch 1993 9 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 11-16 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE93-019624; UCRL-JC-112554; CONF-930722-31) Avail: CASI HC A02

Several years ago neon-like titanium (Z = 22) was made to lase at 326 A on the 3p yields 3s (J = 0 yields 1) transition. At the time it was suggested that the lasing may be due to resonantly photo-pumping the neon-like titanium 2p yields 4d lines using 3s yields 2p and 3d yields 2p lines in carbon-like and nitrogen-like titanium which results in lasing on the 3p yields 3s transition in neon-like titanium. The strongest argument for this explanation was that adjacent elements (scandium and vanadium) did not lase while titanium was unique in having the above mentioned resonance. In addition a pre-pulse was required to make the titanium lase, suggestive of the formation of a low density plasma, and the plasma was very overstripped, so the above mentioned pump lines should be quite strong for photo-pumping. We have re-investigated this laser system and will present results which show lasing on the 3p yields 3s (J = 0 yields 1) transition in neon-like chromium (Z = 24), iron (Z = 26), and nickel (Z = 28) at 285, 255, and 231 A respectively. This destroys the myth of titanium being unique and makes highly unlikely that the previously mentioned photo-pumping mechanism is playing a significant role in the titanium laser. The chromium, iron, and nickel experiments all require a pre-pulse in order to lase and our calculations suggest that the pre-pulse is an exciting new way to create a uniform low density plasma when illuminating a thick slab target. This allows the proper conditions for gain and laser propagation for low Z neon-like ions and may also be applicable to other systems such as low Z nickel-like ions. We also will present experiments done on other low-Z materials and offer an explanation as to how the hyperfine effect is destroying the gain of neon-like ions with odd Z. DOE

EFFECT OF BANDWIDTH ON BEAM SMOOTHING AND FREQUENCY CONVERSION AT THE THIRD HARMONIC OF THE NOVA LASER
D. M. Pennington, M. A. Henesian, S. N. Dixit, H. T. Powell, C. E. Thompson, and T. L. Weiland May 1993 13 p Presented at the OE/LASE 1993: International Society for Optical Engineering (SPIE) Conference, Los Angeles, CA, 13-23 Jan. 1993
(Contract W-7405-eng-48)
(DE93-019917; UCRL-JC-111593; CONF-930159-56) Avail: CASI HC A03/MF A01

We present the results of experiments performed on the Nova laser system to determine the effect of bandwidth on third harmonic (3 omega) frequency conversion and beam smoothing by spectral dispersion (SSD). Our experiments utilized a wide bandwidth fiber optic cross-phase modulated (XPM) source and a narrower bandwidth microwave modulated (FM) source, each centered at 1053 nm (1 omega). The FM source produced approximately 2 cm(exp -1) of bandwidth, modulated at 3 GHz; the XPM bandwidth was varied from 5 to 15 cm(exp -1), modulated by the temporally noisy output of a multimode Nd:glass laser (less than or equal to 500 GHz). The FM beam showed no evidence of self-phase modulation in the laser chain produced by intensity fluctuations, and 1 omega bandwidth was tripled upon conversion to 3 omega (2-6 cm(exp -1)). The 1 omega XPM bandwidth increased by greater than or equal to 25% due to self-phase modulation in the laser chain (16-22 cm(exp -1)) due to it's relative noisy temporal structure. Over 50% of the 1 omega XPM bandwidth was transferred to the 3 omega beam (22-36 cm(exp -1)), yielding 0.13% bandwidth at 3 omega. The maximum intrinsic narrowband 3 omega frequency conversion obtained using a type-II/type-II KDP crystal array was 62%. The intrinsic efficiency obtained at the Nova 10-beam chamber is typically greater than 65%. We have developed broadband frequency conversion codes and broadband pulse simulations to model our results,

and have obtained good agreement with experiment. Using a random phase plate without bandwidth, we obtained a smoothing level, sigma/I approximately 0.79, defined by the rms variance normalized with respect to the average intensity. This is less than the theoretically expected value of one for an ideal speckle pattern, and could be evidence of polarization smoothing as a result of focus lens birefringence. With spectral dispersion and RPP we demonstrated an excellent level of smoothing with the XPM source. DOE

A Free-Electron Laser (FEL) provides a convenient method of reaching short wavelengths by resonating with an input source at the fundamental wavelength while providing bunching at a harmonic of the fundamental. Recently schemes have been proposed that use two wiggler segments, one resonant at the fundamental to pre-bunch the beam, the other lasing at the desired (third) harmonic. A similar effect, with some advantages and some disadvantages, can be achieved using the Multi-Cavity FEL (MC/FEL). The MC/FEL employs several short cavities, operating in an oscillator-like manner, to achieve high output power. In this paper we consider the use of the MC/FEL as a means of generating harmonics. We investigate the competitiveness of this option in comparison with other harmonic generation schemes, in terms of the total wiggler length needed, the saturated power achieved, and the restrictions imposed by mirror reflectivity. VARIABLE-FIELD PERMANENT MAGNET DIPOLE
D. B. Barlow, R. H. Kraus, Jr., and R. E. Meyer 1993 4 p Presented at the 13th International Conference on Magnet Technology, Victoria, Canada, 20-24 Sep. 1993
(Contract W-7405-eng-36)
(DE94-000800; LA-UR-93-3237; CONF-930926-5) Avail: CASI HC A01/MF A01

A new concept for a variable-field permanent-magnet dipole (VFPMD) has been designed, fabricated, and tested at Los Alamos. The VFPMD is a C-shaped sector magnet with iron poles separated by a large block of magnet material (SmCo). The central field can be continuously varied from 0.07 T to 0.3 T by moving an iron shunt closer or further away from the back of the magnet. The shunt is specially shaped to make the dependence of the dipole field strength on the shunt position as linear as possible. The dipole has a 2.8 cm high by 8 cm wide aperture with approximately 10 cm long poles. DOE

PHASE SCREENS FOR THE CONTROL OF THE FOCAL IRRADIANCE OF THE NOVA LASER
J. K. Lawson, S. N. Dixit, D. Eimerl, M. A. Henesian, K. R. Manes, A. J. Morgan, H. T. Powell, I. M. Thomas, J. B. Trenholme, and B. W. Woods 17 Sep. 1993 9 p Presented at the OE/LASE 1993 International Society for Optical Engineering Conference, Los Angeles, CA, 13-23 Jan. 1993
(DE94-001067; UCRL-JC-111445; CONF-930159-58) Avail: CASI HC A02/MF A01

The authors report on the design and fabrication of continuous contour (kinoform) phase plates for homogenizing the focal plane irradiance of high-power, inertial confinement fusion laser systems. These kinoform phase plates are designed using an iterative algorithm. They offer the flexibility of controlling the overall shape of the far-field irradiance profile and the ability to concentrate the energy within a central region of the focal profile. These properties make kinoforms superior to the conventional, binary random phase plates for many applications. Potential methods for fabrication of such kinoform phase plates are discussed. DOE

INFRARED FEL PHOTOCHEMISTRY: MULTIPLE-PHOTON DISSOCIATION OF FREON GAS
B. E. Newnam, J. W. Early, and J. L. Lyman 1993 14 p Presented at the 15th International Free Electron Laser Conference, The Hague, Netherlands, 23-27 Aug. 1993
(Contract W-7405-eng-36)
(DE94-000817; LA-UR-93-3419; CONF-930855-8) Avail: CASI HC A03/MF A01

Wavelength tunability, synchrotron sidebands, and picosecond pulse structure are inherent FEL characteristics that should be advantageous for photochemistry involving infrared multiple-photon photodissociation. Tuned to an absorption resonance, the FEL sideband structure will overlap the broad, excited-state spectral absorption and should lead to enhanced dissociation. The Los Alamos APEX FEL was operated with and without sidebands to test this hypothesis on CFCl3 (Freon 11), an inert chlorofluorocarbon widely used in refrigeration systems and one of the gases implicated as depleting the ozone in the Earth's stratospheric layer. The FEL wavelength was set at the C-Cl stretch absorption resonance at 11.8-microns, the oscillator cavity length was detuned first to minimize and then to maximize the spectral bandwidth, and the beam was focused through a pair of test cells (1.0 Torr Freon + 1.7 Torr air). Comparison of final and initial absorbance spectra indicated the CFCl3 photodissociation yield was 1.2% for the cell exposed with sideband spectra (3% FWHM) and 9-ns micropulse separation. Negligible effect was seen without sidebands, albeit at lower total beam fluence. Although the result of this single experiment is not large enough to be conclusive, it does provide a basis for optimizing the FEL temporal and spectral parameters to attain higher photodissociation yield in future tests. (DE94-000518; RFP-4768) Avail: CASI HC A07/MF A02

The goal of this paper is to study the effects of power level and distribution on thermocapillary induced weld shape and of arc factors on weld shape. Thermocapillarity is apparent in both conduction mode electron beam welds (EBW) and gas tungsten arc (GTA) welds, particularly in the former. A non-Gaussian arc distribution is suggested to account for the differences between the two welding processes. At higher current levels (200-300 A), plasma shear force also contributes to weld shape development. Evidence suggests that thermocapillary flow reversal is not a factor in normal GTA welds; EBW flow reversal occurs only at high power density levels where the keyhole mode is present. DOE

(DE93-019204; CONF-930722-21) Avail: CASI HC A03/MF A01

A new, machine mounted aspheric metrology device designed to measure a broad range of figures without the use of auxiliary optics is addressed. A prototype device, based on the classical Hartmann test, called a Hartmann Optical Surface Tester (HOST) was evaluated on a single point diamond turning machine. Design, initial testing, and validation data from reference spheres, and two types of aspheres are discussed. Results of a simulation model for estimating acceptable alignment errors for the HOST on the diamond turning machine are also presented. Peak-to-valley measurement uncertainty on the test optics was found to be better than 0.08 microns. DOE

DESIGN OF A CONTROLLABLE PITCH UNDERWATER THRUSTER SYSTEM M.S. Thesis
Robert W. Keefe Aug. 1993 114 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271140) Avail: CASI HC A06

Control systems for underwater vehicles have reached the level of sophistication where they are limited by the dynamic performance of the thrust actuators. Standard fixed-pitch propellers have been shown to have very poor dynamic characteristics, particularly at low thrust levels. The dynamic response of a fixed-pitch propeller is dependent upon highly non-linear transients encountered while the shaft speed approaches its steady-state value. This thesis proposes the use of a controllable pitch propeller system to address this problem. A controllable pitch propeller varies the amount of thrust produced by varying the pitch angle of the blades at a constant shaft speed. The bandwidth of this type of thrust actuator would be dependent primarily on the speed at which the pitch angle of the blades are changed. A variable pitch propeller system suitable for retrofit into an ROV is designed and built. The system is designed for maximal pitch angle bandwidth with low actuator power consumption. DTIC

This interim report continues with the research effort on advanced adaptive controls for space robotics systems. In particular, previous results developed by the principle investigator and his research team centered around fuzzy logic control (FLC) in which the lack of knowledge of the robotic system as well as the uncertainties of the environment are compensated for by a rule base structure which interacts with varying degrees of belief of control action using system measurements. An on-line adaptive algorithm was developed using a single parameter tuning scheme. In the effort presented, the methodology is further developed to include on-line scaling factor tuning and self-learning control as well as extended to the multi-input, multi-output (MIMO) case. Classical fuzzy logic control requires tuning input scale factors off-line through trial and error techniques. This is time-consuming and cannot adapt to new changes in the process. The new adaptive FLC includes a self-tuning scheme for choosing the scaling factors on-line. Further the rule base in classical FLC is usually produced by soliciting knowledge from human operators as to what is good control action for given circumstances. This usually requires full knowledge and experience of the process and operating conditions, which limits applicability. A self-learning scheme is developed which adaptively forms the rule base with very limited knowledge of the process. Finally, a MIMO method is presented employing optimization techniques. This is required for application to space robotics in which several degrees-of-freedom links are commonly used. Simulation examples are presented for terminal control - typical of robotic problems in which a desired terminal point is to be reached for each link. Future activities will be to implement the MIMO adaptive FLC on an INTEL microcontroller-based circuit and to test the algorithm on a robotic system at the Mars Mission Research Center at North Carolina State University. A system for coupling an orbital replacement unit (ORU) to a space station structure via the actions of a robot and/or astronaut is described. This system provides mechanical and electrical connections both between the ORU and the space station structure and between the ORU and the ORU and the robot/astronaut hand tool. Alignment and timing features ensure safe, sure handling and precision coupling. This includes a first female type spline connector selectively located on the space station structure, a male type spline connector positioned on the orbital replacement unit so as to mate with and connect to the first female type spline connector, and a second female type spline connector located on the orbital replacement unit. A compliant drive rod interconnects the second female type spline connector and the male type spline connector. A robotic special end effector is used for mating with and driving the second female type spline connector. Also included are alignment tabs exteriorally located on the orbital replacement unit for berthing with the space station structure. The first and second female type spline connectors each include a threaded bolt member having a captured nut member located thereon which can translate up and down the bolt but are constrained from rotation thereabout, the nut member having a mounting surface with at least one first type electrical connector located on the mounting surface for translating with the nut member. At least one complementary second type electrical connector on the orbital replacement unit mates with at least one first type electrical connector on the mounting surface of the nut member. When the driver on the robotic end effector mates with the second female

type spline connector and rotates, the male type spline connector and the first female type spline connector lock together, the driver and the second female type spline connector lock together, and the nut members translate up the threaded bolt members carrying the first type electrical connector up to the complementary second type connector for interconnection therewith. A unique structure for constructing the emissive patch of a spaceborne radiative cooler is shown. The structure has very high emissivity for all angles up to a designed-in maximum angle and near zero emissivity for greater angles. The structure also allows the use of high emissivity, nonconducting paints while fully complying with the NASA Electrostatic Discharge Susceptibility requirements for spacecraft. To accomplish these tasks, two previous disadvantages of prior art methods are addressed; eliminating background thermal radiation sources and problems concerning the high emissivity paints used in association with the black body radiator. A reflector consisting of an array of parabolic concentrators is separated from a black body element by an electrically conductive spacer. The concentrators serve to limit the field of view while the conductive spacer eliminates the need to use a conductive paint on the emissive element.

A DESIGN OPTIMIZATION PROCEDURE FOR EPICYCLIC GEARS

J. D. Andrews Jun. 1993 29 p
(MATHS-Rept-A-188; ETN-93-94906) Avail: CASI HC A03/MF A01

A design optimization procedure to increase the working life of epicyclic gears units by minimizing the tensile fillet stresses experienced in the gear system components is described. An objective function is formulated together with 69 constraints which ensure that a functional system design is achieved. For the example presented, the optimum design was produced in only three iterations and reduced the maximum stress in any component by 54%. ESA

DISENGAGABLE ADAPTER FOR AN OPTICAL FIBER CONNECTOR Patent Application

Gair D. Brown, inventor (to Navy) and Michael A. Richardson, inventor (to Navy) 18 Mar. 1993 18 p
(AD-D015959; US-Patent-Appl-SN-033223; Navy-Case-75029) Avail: CASI HC A03/MF A01

A disengagable adapter for mechanically coupling optical fibers is provided. The disengagable adapter separates into two complementary receptacle parts. Each receptacle part receives through a bore a single optical-fiber located within an optical-fiber connector plug. Each receptacle part attaches to and securely holds a different connector plug. The receptacle parts mate with each other in a complementary fashion and thereby connect the two optical fiber connector plugs together. These connector plugs accordingly align the two optical fibers located within the plugs. The optical fibers can be separated either by demating the complementary parts or by disconnecting one side of the adapter from its connector plug. Mounting the complementary parts to a plate facilitates multiple, simultaneous connections. DTIC

A device for mounting a data transmission apparatus to a rotating, tapered, and instrumented shaft is provided. This device permits attachment without interfering with shaft rotation or the accuracy of data output, and prevents both radial and axial slippage of the data transmission apparatus. The mounting device consists of a sleeve assembly which is attached to the shaft by means of clamps that are situated at some distance removed from the instrumented area of the shaft. The data transmission device is secured to the sleeve such that the entire assembly rotates with the shaft. Shim adjustments between sleeve sections assure that a minimum compressive load is transferred to the instrumented area of the shaft and a rubber lining is affixed to a large portion of the interior surface of the sleeve to absorb vibration.

US-Patent-Class-212-196; US-Patent-Class-212-262;
Int-Patent-Class-B66C-23/76) Avail: US Patent and Trademark Office

The invention is a counter-balanced, multiple cable construction crane. The apparatus for hoisting payloads comprises a crane having a lifting means, the lifting means comprising an end effector means and three suspension means or cables. One end of each cable attaches to a different winding means located on the lifting means, and the other end of each cable attaches to a different point on the end effector, such that the three cables have a theoretical point of convergence with this point corresponding to the center of mass of the payload. Three controls command rotation of the winding means to a predetermined position. Accordingly, the crane provides precise and autonomous positioning of the payload without human guidance. The crane further comprises a counter-balancing means. Two controls position the counter-balancing means to offset the overturning moment which arises during the lifting of heavy payloads.

THREE POINT LEAD SCREW POSITIONING APPARATUS FOR A CAVITY TUNING PLATE Patent

Frank S. Calco, inventor (to NASA) 7 Sep. 1993 7 p Filed 27 Jan. 1992 Supersedes N92-17678 (30 - 8, p 1307)
(NASA-Case-LEW-15216-1; US-Patent-5,243,310;
US-Patent-Appl-SN-826547; US-Patent-Class-333-233;
US-Patent-Class-315-5.54; Int-Patent-Class-H01P-7/06) Avail: US Patent and Trademark Office

Three lead screws are provided for adjusting the position of a traversing plate. Each of the three lead screws is threaded through a collar that is press fitted through the center of one of three pinion gears. A sun gear meshes with all three pinion gears and transversely moves the three lead

screws upon actuation of a drive gear. The drive gear meshes with the sun gear and is driven by a handle or servomotor. When the handle or servomotor rotates the drive gear, the sun gear rotates causing the three pinion gears to rotate, thus, causing transverse movement of the three lead screws and, accordingly, transverse movement of the transversing plate. When the drive gear rotates, the traversing plate is driven in and out of a microwave cavity. Thus, the length or size of the cavity can be tuned while maintaining the traversing plate in an exact parallel relationship with an opposing plate on another end of the cavity.

Int-Patent-Class-F16B-39/00) Avail: US Patent and Trademark Office

In the space shuttle, a cargo bay storage rack was required which was to be manufactured from a metal-plastic composite and bolted to a cargo structure. Following completion, utilization of the rack was disallowed due to tolerances, that is, the size differences between the outside bolt diameter and the inside hole diameter. In addition to the space shuttle problem there are other close tolerance requirements for bolts. Such environments often benefit from close tolerance bolting. Frequently such fabrication is not cost effective. Consequently there is a need for means of achieving close tolerances between bolts and bolt holes. Such means are provided. After compressing the elements together a strong rigid plastic, ceramic, or ceramic plastic fluid is forced into a channel extending through the bolt.

US-Patent-Class-118-500; US-Patent-Class-118-730;
US-Patent-Class-269-71; Int-Patent-Class-B05C-13/00) Avail: US Patent and Trademark Office

In vacuum plasma spraying a turntable must be provided which not only makes it possible to rotate and tilt a heavy workpiece, but to operate at vacuum plasma temperatures to do so. In the vacuum plasma coating of large parts such as combustion chambers of rocket engines, the workpiece must not only be rotated, but it must be tilted. Hence, the turntable must be capable not only of supporting heavy parts, but of angulating such heavy workpieces. And this must be done without drive means failure due to extremely high temperatures under which the turntable mechanism is operated. A turntable mechanism is provided which is capable of operating under such conditions. For cooling the turntable drive mechanism, internal cooling means are included.

MICROSCOPIC MODELING OF TRIBOLOGICAL AND INTERFACIAL PHENOMENA Final Report, 1 Jan. 1990 - 31 Jul. 1993

Uzi Landman 31 Jul. 1993 108 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant AF-AFOSR-0117-90)
(AD-A271864; AFOSR-93-0817TR) Avail: CASI HC A06

Atomic-scale energetics and structural and dynamical mechanisms underlying interfacial processes--in particular for systems when two materials are brought together, separated, or slide against each other--are of fundamental importance for basic science and technology in areas such as interfaces, confined fluids, adhesion, tribology, junctions, lubrication, wear, surface modifications, and nano technology. Our research is focused on the development and implementation of methods of atomistic molecular dynamics simulations and applications to tribological, lubrication and related interfacial phenomena. The main research results are as follows: Simulations of the consequences of tip-substrate interactions, adhesive junction formation, nano-indentation, and force versus distance hysteresis. These investigations motivated experimental studies yielding results in agreement with the theoretical predictions. Furthermore, the results permit critical evaluation and extension of continuum treatments. Investigations of structural and dynamical properties of confined model lubricants (alkanes); formation of liquid junctions, interfacial segregation in mixtures, atomistic mechanisms of cavitation and collapse, and dependence of lubricant rheology on molecular architecture. ACTIVELY CONTROLLED SHAFT SEALS FOR AEROSPACE APPLICATIONS Semiannual Status Report, Jul. - Dec. 1993

Richard F. Salant Dec. 1993 36 p

(Grant NAG3-974)
(NASA-CR-194759; NAS 1.26:194759; E25-666) Avail: CASI HC A03/MF A01

An electronically controlled mechanical seal for use as the purge gas seal in a liquid oxygen turbo pump has been fabricated and tested under transient operating conditions. The thickness of the lubricating film is controlled by adjusting the coning of the carbon face. This is accomplished by applying a voltage to a piezoelectric actuator to which the carbon face is bonded. The seal has been operated with a closed-loop control system that utilizes either the leakage rate or the seal face temperature as the feedback. Both speed and pressure transients have been imposed on the seal. The transient tests have demonstrated that the seal is capable of maintaining low leakage rates while limiting the face temperatures.

COLD-START MINIDIESEL ENGINE DEVELOPMENT Final Report, Jul. 1991 - Mar. 1992

Conrad Collins Sep. 1993 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DAAK60-91-C-0093; DA Proj. 1L1-62786-AH-98)
(AD-A271064; Natick-TR-93/039) Avail: CASI HC A03

Military mission performance in a chemically contaminated environment necessitates the wearing of chemically impermeable protective garments. Soldiers encapsulated in these protective garments will succumb to heat stress in a hot environment. Consequently, a microclimate cooling system is being developed. In the design, a vapor compression cycle chills water which is then circulated over the body to absorb heat via a cooling garment. The engine, the prime mover in the system, is a major component. Commercially available engines of approximately 0.5 hp at 4000 rpm, the

required size, include model aircraft engines and small outdoor power equipment (string trimmer) engines. However, these engines do not run on JP-8 or diesel fuel, a requirement for military use. Design, evaluation, and results of three engines are detailed. These include: the potential of a high compression, carbureted, glow plug engine operating on diesel fuel; the potential of a high compression, spark assist, fuel injected engine operating on diesel fuel; and a true high compression, fuel injected engine operating on diesel fuel. A control valve includes a body defining a central cavity arranged between a fluid inlet and outwardly-diverging first and second fluid outlets respectively disposed in a common transverse plane. A valve member is arranged in the cavity for rotation between first and second operating positions where a transverse fluid passage through the valve member alternatively communicates the fluid inlet with one or the other of the fluid outlets. To minimize fluid turbulence when the valve member is rotated to an alternate operating position, the fluid passage has a convergent entrance for maintaining the passage in permanent communication with the fluid inlet as well as an oblong exit opening with spaced side walls for enabling the exit opening to temporarily span the first and second fluid outlets as the valve member is turned between its respective operating positions.

Hassan Saghir 1992 228 p In FRENCH
(ECL-92-40; ETN-93-94596) Avail: CASI HC A11/MF A03

A study to create a computer model to predict the consequences of modifications to engine construction, and those of engine running conditions, on engine performance is reported. The results illustrate the complex interactions between engine components which the engineer must take into account. A kinematical and dynamical analysis of the piston/piston rings/cylinder wall system was coupled to an engine simulation model to develop a model of gas flow through the piston ring crevices. An analytical method to solve the equation for the axial movement of a piston ring, which the model uses to calculate the piston ring positions, is used. The oil flow around the piston rings was studied and an estimation of the flow rate of oil leaking into the combustion chamber is proposed. The experimental analysis was performed on a single cylinder spark ignition engine. The measured blowby gas measurements and the model predictions were compared, and were found to be in reasonable agreement over a wide range of engine operating conditions and ring sets. A simple statistical study of cyclic dispersion in the combustion chamber was also carried out, which enabled the effect of cyclic dispersion to be incorporated in numerical simulation. ESA

PROCESS AND APPARATUS FOR THE RELEASE OF A PRESTRESS INITIALLY APPLIED TO A MECHANISM SUCH AS A BEARING ON BOARD A SPACE VEHICLE Patent Application
Jean-Pierre Schoeffter, inventor (to SNIA) 12 Jan. 1992 13 p
(CA-Patent-Appl-SN-2,020,909; Int-Patent-Class-F16C-23/00;
CTN-93-60669) Copyright Avail: Micromedia Ltd., Technical Information Centre, 165 Hotel de Ville, Place du Portage, Phase 2, Hull, Quebec J8X 3X2, Canada HC/MF

In space vehicles, mechanisms such as ball bearings are subject to an initial preload or prestress enabling them to withstand the vibrations caused by the launch and without leading to any clearance or play. A member made from a shape memory material, for example, makes it possible under the effect of its elongation to release the preload when the vehicle is in the operational mode. The control of the release can take place by means of a heating resistor, whose energization leads to the member clearing its shape change temperature and releasing the prestress. The heating can also be done by means of solar energy. The process and apparatus of this invention makes it possible in a particularly simple and non-constraining manner to release the prestress applied to a mechanism during launch without incurring any risk of deterioration to the mechanism during the launch phase and without the need to use a rigid member linked with a pyrotechnic control. HEAT REGENERATIVE EXTERNAL COMBUSTION ENGINE Patent
Anthony W. Duva, inventor (to Navy) 19 Oct. 1993 7 p Filed 23 Mar. 1993
(AD-D015965; US-Patent-5,253,473; US-Patent-Appl-SN-035867;
US-Patent-Class-60-39.462) Avail: US Patent and Trademark Office

A heat regenerative external combustion engine is disclosed. The engine includes fuel inlet means which extends along the exhaust passage and/or combustion chamber in order to preheat the fuel, To provide for preheating by gases in both the combustion chamber and the exhaust passage, the combustion chamber is arranged annularly around the drive shaft and between the cylinders. This configuration also is advantageous in that it reduces the noise of combustion. The engine of the invention is particularly well-suited for use in a torpedo. DTIC

SELF LOCKING SET SCREW Patent
Michael A. Tucchio, inventor (to Navy) 14 Sep. 1993 4 p Filed 3 Feb. 1993
(AD-D015969; US-Patent-5,244,323; US-Patent-Appl-SN-012837;
US-Patent-Class-411-271) Avail: US Patent and Trademark Office

A threaded, locking set screw with standard outer dimensions having a threaded body, an expansion plug, and a retaining wedge is described. The threaded body has a tapered cavity at its bottom end. The expansion plug and retaining wedge are inserted into the cavity in the body. The base of the plug extends from the cavity, and the plug is held in place by a force fit between the wedge and a retaining slot in the body. When the set screw is tightened against a part, the plug is forced into the cavity. Because of a locking taper between the plug and the cavity, the plug exerts an outward force on the inner surface of the cavity causing the set screw body to expand radially, thus, locking the set screw in place. ANALYSIS OF A DIESEL-ELECTRIC HYBRID URBAN BUS SYSTEM
W. W. Marr, R. R. Sekar, and M. C. Ahlheim (Regional Transportation Authority, Chicago, IL.) 1993 6 p Presented at the 1993 SAE Future Transpotation Technology Conference, San Antonio, TX, 9-12 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019514; ANL/ES/CP-80046; CONF-9308143-4) Avail: CASI HC A02/MF A01

A hybrid bus powered by a diesel engine and a battery pack was analyzed over an idealized bus-driving cycle in Chicago. Three hybrid configurations, two parallel and one series, were evaluated. The results indicate that the fuel economy of a hybrid bus, taking into account the regenerative braking, is comparable with that of a conventional diesel bus. Life-cycle costs are slightly higher because of the added weight and cost of the battery. DOE

UTILIZATION OF METALS TO IMPROVE THE LUBRICATION OF CERAMIC LOAD-BEARING DEVICES Topical Report, 1 Sep. 1987 - 1 Dec. 1990
C. I. Chen, E. E. Klaus, and J. L. Duda Apr. 1993 109 p
(Contract GRI-5084-238-1302)
(PB93-202448; CAM-9302; GRI-93/0048) Avail: CASI HC A06/MF A02

The objective of the study is to determine which potential constituents can be incorporated into ceramic bearing surfaces in order to enhance rates of film formation at elevated temperatures (700 C). Tricresyl Phosphate (TCP) and Trimethylolpropane Triheptanoate (TMPTH) were chosen as the vapor-delivered lubricants, and a wide variety of metals were evaluated using the vapor deposition test. The results of the study indicate that a small amount of metal incorporated into the ceramic surface can promote the formation of a lubricating film. Also, it is possible that a lightly loaded ferrous alloy-bearing separator or retainer could be incorporated in a ceramic rolling element bearing as a source of catalytic activity for enhanced deposit formation. LUBRICATED WEAR OF STEEL-CERAMIC AND CERAMIC-CERAMIC SYSTEMS Topical Report, 1 Jun. 1986 - 1 Sep. 1990
W. T. Wu, E. E. Klaus, and J. L. Duda Apr. 1993 255 p
(Contract GRI-5084-238-1302)
(PB93-202356; CAM-9303; GRI-93/0049) Avail: CASI HC A12/MF A03

The goals of the program were to develop methods of measuring wear in the four-ball wear tester using lubricants in the fully flooded, vapor phase with condensation and vapor phase procedures with a variety of lubricant types. The use of ceramic discs as a substitute for balls in the friction dynamometer was also developed in the program. These studies show that changes in bearing systems from steel-on-steel to steel-on-ceramic can be made without changing the lubricant-additive systems now used in natural gas fired engines. The studies also showed that vapor phase lubrication could be substituted for liquid lubricants without sacrifice in performance in the four-ball wear tester. NTIS

Heavy-duty natural gas engines run hot and relatively dry. This provides lubricant and lubrication problems in the piston ring-cylinder and valve areas. A potential materials solution to this problem is the use of ceramic bearing surfaces. The objective of the project was the investigation of the wear characteristics and surface interactions of lubricants on ceramic bearing surfaces and to compare these results with the behavior of the same lubricants on steel surfaces. The temperature range of interest in these comparisons is 200 to 370 C using a four-ball wear tester. NTIS

DETAILED STUDY OF OXIDATION/WEAR MECHANISM IN LOX TURBOPUMP BEARINGS
T. J. Chase (National Academy of Sciences - National Research Council, Washington, DC.) and J. P. McCarty Dec. 1993 112 p
(NASA-TM-108434; NAS 1.15:108434) Avail: CASI HC A06/MF A02

Wear of 440C angular contact ball bearings of the phase 2 high pressure oxygen turbopump (HPOTP) of the space shuttle main engine (SSME) has been studied by means of various advanced nondestructive techniques (NDT) and modeled with reference to all known material, design, and operation variables. Three modes dominating the wear scenario were found to be the adhesive/sheer peeling (ASP), oxidation, and abrasion. Bearing wear was modeled in terms of the three modes. Lacking a comprehensive theory of rolling contact wear to date, each mode is modeled after well-established theories of sliding wear, while sliding velocity and distance are related to microsliding in ball-to-ring contacts. Microsliding, stress, temperature, and other contact variables are evaluated with analytical software packages of SHABERTH(TM)/SINDA(TM) and ADORE(TM). Empirical constants for the models are derived from NIST experiments by applying the models to the NIST wear data. The bearing wear model so established precisely predicts quite well the average ball wear rate for the HPOTP bearings. The wear rate has been statistically determined for the entire population of flight and development bearings based on Rocketdyne records to date. Numerous illustrations are given. Author (revised)

SOME EVIDENCE ON DETERMINANTS OF FUEL ECONOMY AS A FUNCTION OF DRIVING CYCLE AND TEST TYPE
D. J. Santini and J. Anderson 1993 14 p Presented at the 1993 Society of Automotive Engineers (SAE) Future Transportation Technology Conference, San Antonio, TX, 9-12 Aug. 1993
(Contract W-31-109-eng-38)
(DE93-019511; ANL/ES/CP-78818; CONF-9308143-3) Avail: CASI HC A03/MF A01

Statistical methods are used with 107 vehicles whose fuel economy was presented and reported for five test types in a single publication by Consumers Union (CU) for 1986-1988 vehicles. Standard loglinear statistical formulations (i.e., multiplicative models of interactions) are used with data from this and supplementary sources to develop coefficients estimating the percent fuel economy gain per percent change in engine/vehicle design characteristic. The coefficients are developed for the five different test conditions evaluated by CU and are compared with each other on the basis of attributes of the tests. The insights of engineering models are used to develop expectations regarding the shift in size of coefficients as driving cycles change. In both the engineering models and the statistical model, the effect of weight is estimated to be higher in urban driving than in highway driving. For two test categories - field tests and dynamometer

tests - the benefits of weight reduction are statistically estimated to be greatest in urban driving conditions. The effect on idle fuel flow rate of designing vehicles to hold performance roughly constant by maintaining power per kilogram and/or displacement per kilogram is examined, and its implication for the size of the weight effect is simply approximated from Sovran's 1983 engineering model results. The fuel-economy-decreasing effect of the desire for performance is estimated to be somewhat larger in the statistical analysis than in the NAS study, when engine technology is held constant. DOE

THE RELATIVE NOISE LEVELS OF PARALLEL AXIS GEAR SETS WITH VARIOUS CONTACT RATIOS AND GEAR TOOTH FORMS

Raymond J. Drago (Boeing Helicopter Co., Philadelphia, PA.), Joseph W. Lenski, Jr. (Boeing Helicopter Co., Philadelphia, PA.), Robert H. Spencer (Boeing Helicopter Co., Philadelphia, PA.), Mark Valco (Army Research Lab., Cleveland, OH.), and Fred B. Oswald Dec. 1993 17 p Presented at the Fall Technical Meeting of the American Gear Manufacturers Association, Detroit, MI, 14-15 Oct. 1993

(DA Proj. 1L1-6211-A-47-A; RTOP 505-62-10)

(NASA-TM-106431; E-8273; NAS 1.15:106431; ARL-TR-318) Avail: CASI HC A03/MF A01

The real noise reduction benefits which may be obtained through the use of one gear tooth form as compared to another is an important design parameter for any geared system, especially for helicopters in which both weight and reliability are very important factors. This paper describes the design and testing of nine sets of gears which are as identical as possible except for their basic tooth geometry. Noise measurements were made at various combinations of load and speed for each gear set so that direct comparisons could be made. The resultant data was analyzed so that valid conclusions could be drawn and interpreted for design use. Author

As part of this involvement, Solar intends to design and commercialize a unique gas turbine system that promises high cycle efficiencies and low exhaust emissions. This engine of approximately 12-MW will be targeted for the dispersed power markets both urban and rural. Goals of 50% thermal efficiency and 8 parts-per-million by volume (ppmv) nitrogen oxide emissions were established. Reliability, availability, and maintainability (RAM) will continue to be the most important factors in the competitive marketplace. The other major goal adopted was one of reducing the cost of power produced by 10%. This reduction is based on the cost of power (COP) associated with today's engines that lie in the same horsepower range as that targeted in this study. An advanced cycle based on an approximation of the Ericsson Cycle was adopted after careful studies of a number of different cycles. This advanced intercooled, recuperated engine when fired at 2450 F will be capable of meeting the 50% efficiency goal if the cooling air requirements do not exceed 7% of the total air flow rate. This latter qualification will probably dictate the use of ceramic parts for both the nozzle guide vanes and the turbine blades. Cooling of these parts will probably be required and the 7% cooling flow allowance is thought to be adequate for such materials. Analyses of the cost of power and RAM goals show that the installed cost of this advanced engine can be approximately 50% above today's costs. This cost is based on $4.00 per million Btu fuel and a COP reduction of 10% while maintaining the same RAM as today's engines. DOE

PERFORMANCE CALCULATIONS AND RESEARCH DIRECTION FOR A WATER ENHANCED REGENERATIVE GAS TURBINE CYCLE

L. H. Rogers and D. H. Archer (Carnegie-Mellon Univ., Pittsburgh, PA.) 1993 9 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993

(DE93-019866; DOE/METC-C/93/7097; CONF-930804-18) Avail: CASI HC A02/MF A01

A cycle has been conceived that combines compressor cooling, humidification, and regenerative air heating with the added enhancement of direct injection of water into the air flow. In this cycle it is proposed that a fine mist of water be injected into the compressor air stream and a spray or film of water into the regenerator air stream. Water injection into the compressor air flow realizes several benefits: it cools the air flow, reducing the power required for compression and increasing the potential for exhaust heat recovery; it adds mass to the air stream, increasing the power produced by expansion; and it reduces the amount of cooling bleed air required by increasing the specific heat and decreasing the temperature of the cooling air stream. The greatest benefit would be derived from spraying a fine mist of water directly into the existing air flow into or before the compressor so that cooling and compression would occur simultaneously. This may be accomplished by entraining the water droplets in the inlet air flow or by introducing the water in stages during compression. An alternative and less technically challenging approach is to extract the air stream to a saturation chamber and then reintroduce the air stream into the compressor. This approach is not as desirable because it would increase the equipment cost and add a significant pressure drop penalty. The second use of water in this cycle is in water-assisted regeneration. The heat capacity of the hot stream in regenerators is greater than the heat capacity of the cool stream because of the increased mass flow and specific heat of the combustion products. This imbalance leads to a less than ideal exhaust heat recovery since the cool air stream is unable to absorb all of the available heat. If water is injected into the cool stream in the regenerator, some of the available heat is used to vaporize the water, allowing additional heat recovery and also adding mass to the air flow. Also, the effectiveness of the heat exchanger can be increased, and the cost reduced, by injecting the water as early as possible in the flow, keeping the cool stream temperature low and thus maximizing the temperature difference across the regenerator. ACTIVE DAMPING OF OSCILLATIONS IN A LONG COMPLIANT MANIPULATOR LINK

C. P. Baker, M. S. Evans, D. J. Trudnowski, and D. P. Magee (Georgia Inst. of Tech., Atlanta.) Jul. 1993 9 p Presented at the 9th International Conference on Mathematical and Computer Modeling, Oxford, England, 26-29 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by poor print

(Contract DE-AC06-76RL-01830)

(DE93-018878; PNL-SA-22414; CONF-9307126-1) Avail: Issuing Activity (Department of Energy (DOE))

A flexible manipulator test bed consisting of a fifteen foot long fixed-free compliant beam (representing a compliant manipulator link) with a Shilling Titan II dextrous manipulator mounted on its free end has been constructed at Pacific Northwest Laboratory (PNL). A comprehensive dynamic model which includes flexible body effects has been developed at PNL using a commercially available multibody dynamics code. A linearized version of the model is used to develop control strategies which use inertial forces generated by movements of the dextrous manipulator to damp out induced oscillations in the beam. These control strategies are tested on the model and shown to be feasible, and then implemented in the flexible manipulator testbed. Results from the hardware experiments are analyzed and compared with the model results. DOE

A test program was devised at EPA's National Vehicle and Fuel Emissions Laboratory to evaluate a Tonen ultrasonic fuel atomizer system on a Honda B20 engine using both M85 (85% methanol, 15% hydrocarbons) and M100 (neat methanol) fuels to determine whether cold starting a premixed-charge port injected engine on alcohol fuels at low ambient temperatures can be improved. Modification to the engine's intake manifold was performed at

the Japanese Automotive Research Institute (JARI) in cooperation with the New Energy Development Organization (NEDO) to install heated injectors in close proximity to the ultrasonic atomizers. The engine is also equipped with the stock port injector system intact and functional. Successful M100 cold starts were obtained down to 20 F (-7 C). NTIS

THE EFFECT OF COMPTON SCATTERING ON THE DOUBLE TO SINGLE IONIZATION RATIO IN HELIUM
R. J. Bartlett, M. Sagurton (SFA, Inc., Landover, MD.), J. A. R. Samson (Nebraska Univ., Lincoln.), and Z. X. He (Nebraska Univ., Lincoln.) 1993 15 p Presented at the Double Ionization in He, Argonne, IL, 4 Oct. 1993 (Contract W-7405-eng-36)
(DE94-000884; LA-UR-93-3426; CONF-9310190-1) Avail: CASI HC A03/MF A01

The ratio of double to single ionization in Helium produced by photon impact has been measured for photon energies from 2.1 to 5.5 keV. The measurements suggest that a significant contribution to the single ionization cross section is caused by Compton scattering for energies greater than approximately 3.8 keV. After accounting for the ionizing Compton scattering, the measured ratio is not inconsistent with recent calculations of the asymptotic limit of the ionization ratio caused by photoabsorption which predict a limit near 1.66%. Flexible dynamic analysis of robotic manipulators was conducted using orthogonal polynomials in the assumed-mode method. In the derivation of the system equations, kinematic parameters such as joint displacements, velocities, and accelerations also occur. This necessitates the kinematic analysis of rigid links. The kinetic and potential energy of a link segment are obtained using homogeneous transformation matrices which relate the link coordinate system to the global coordinate frame. These energies are then substituted in Lagrange's equation. The nonlinear dynamic equations are then solved to evaluate the actuator torques required for a prescribed trajectory. The dynamic analysis of flexible manipulators is also carried out by the finite element method where the elemental equations are derived for three different types of beams subjected to gross motion. The resulting nonlinear set of system equations are solved using an iterative numerical integration scheme. To study the effect of contribution of various modes, the nonsymmetric system matrices are diagonalized using the biorthogonality property of the mode shapes of the original and transposed systems. The expressions for the elemental matrices are obtained using a computer simulation package, program listings of which are included. Author (CISTI)

In the development of opto-fluidic systems for flight control, the main bottleneck has been the lack of a suitable optomechanical interface and actuator. A novel optomechanical actuator is proposed, the optohydraulic servovalve (OHS), which could have flight control applications. The device consists of the mating of an optomechanical interface, the optothermic gas cell (Ocell), with a jet pipe servovalve. A review is presented of known optical to mechanical transduction mechanisms; a qualitative and quantitative comparison indicates that the Ocell has superior characteristics for interfacing with a servovalve. The Ocell constitutive relations describing pressure, diaphragm displacement, and bandwidth with respect to input optical power were also developed and verified experimentally. Mathematical models developed for the OHS are described, and it is shown numerically that the OHS can be operated by as little as 10 mW of optical power. Some experimental Ocells were designed and constructed, and it was demonstrated that a pair of Ocells could replace the torque motor in a standard electrohydraulic servovalve and thereby result in a new device. ROBOT LINK AND CONTACT SURFACE DYNAMIC INTERACTION: AN EXPERIMENTAL STUDY OF CONTACT INSTABILITY M.S. Thesis
Yuri Andrew Lawryshyn 29 Apr. 1993 154 p
(ISBN-0-315-83439-0; CTN-94-60952) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The stability of manipulators with structurally compliant links during contact with a surface that exhibits structural compliance is examined. An experimental robot was designed to perform contact task experiments under varying dynamics. The contact surface is part of the Variable Impedance Machine, whose dynamics can be arbitrarily varied to represent any mass spring damper system. A dynamic model of the experimental facility was developed which was programmed to simulate the facility. Results from simulation agreed well with those from experiments. Using singular perturbation theory, a stability formulation was presented in which three dynamic cases were considered: the robot links are much stiffer than the environment; the environment is much stiffer than the links; and the links and environment have equal stiffness. The theory predicted stability for the first case under certain assumptions but was inconclusive for the other two cases. Experiments and simulations showed stability for all three cases. The Product Quality Deficiency Report (PQDR) is a Department of Defense form that identifies deficiencies in the manufacture, repair, or procurement of materiel. It may be used by DoD employees or contractors to identify defects at any point in the item's life. DoD generates nearly 75,000 such deficiency reports each year. In most cases, when a defect is identified, Standard Form (SF) 368 is completed and sent to the activity managing the contract under which the materiel was procured. That activity, usually in conjunction with the contractor, investigates the complaint, attempts to determine a cause and a corrective action, and must make some disposition of the defective materiel. The process is labor- and paper-intensive and time-consuming. Technology can reduce the costs of the process and at the same time improve timeliness by electronically exchanging discrepancy data between activities. Electronic data interchange (EDI) is one technology for electronically passing PQDR data. It is widely used in industry and increasingly within DoD. DMRD 941 defines DoD's commitment to use EDI and cites the PQDR and other discrepancy reports as early candidates for EDI. In this report, we describe how EDI can be linked to changes in PQDR processing practices to provide further improvements. DTIC

DYNAMIC, MULTIAXIAL IMPACT RESPONSE OF CONFINED AND UNCONFINED CERAMIC RODS
J. L. Wise and D. E. Grady 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-040057; SAND-93-1703C; CONF-930676-45) Avail: CASI HC A01/MF A01

A new configuration for impact testing was implemented which yielded time-resolved measurements of the dynamic response of materials undergoing multiaxial strain. With this method, one end of an initially stationary rod (i.e., right circular cylinder) of test material was subjected to planar impact with a flat-faced projectile. The test rod was either free (unconfined) or mounted within a close-fitting sleeve which provided lateral confinement. Velocity interferometer diagnostics monitored the axial (longitudinal) velocity of the rod free end and the transverse (radial) velocity for one or more points on the periphery of the rod or confinement sleeve. Analysis of the resultant velocity records allowed assessment of material properties, such as wave speeds and compressive yield strength, without the requirement of intact recovery of the rod. Data were obtained for alumina (Coors AD-99.5) rods in a series of tests involving variations in confinement and peak impact stress. DOE

SHOCK WAVE INTERACTIONS WITH EXOTHERMIC MIXTURES Final Report, Sep. 1989 - Jan. 1993
K. Iyer 10 Aug. 1993 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-89-C-0037)
(AD-A271149; ARO-27364.2-MS) Avail: CASI HC A02

Instrumented high velocity impact recovery experiments were performed to study solid state reactions in mixtures of nickel and aluminum powders during the passage of shock waves. Excess pressure due to the release of energy from the exothermic reaction was measured for a range of impact velocities. An impact velocity threshold for the initiation of reaction at the reflected shock front was established, and this threshold value was found to be dependent on the particle size of the powder. Microscopic examination of the recovered specimens show features which corroborate the hypothesized extent of a reaction based on pressure measurements. DTIC

AN EQUATION OF STATE FOR SHOCK IN HOMOGENEOUS MATERIALS AND COMPARISON TO SHOCK DATA Final Report, 1 May 1991 - 30 Aug. 1992
J. H. Shively (California State Univ., Northridge.), C. Stein, and R. Robertson Aug. 1993 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A271436; AD-E201663; PL-TR-92-1060) Avail: CASI HC A03

An evaluation of hypervelocity impact data for metals, ceramics, ionic, and polymer materials and water as it leads to an equation of state for solids, is presented. The results indicate that for shock induced pressure, the materials behave as if they are in corresponding states, so that a single equation relates pressure to particle velocity for the entire range of materials investigated. The relationship between shock velocity and particle velocity can be represented by a line with a single slope and with an intercept associated with the bulk sound velocity. Comparisons to solid state theory are made which permit a discussion regarding Grueneisen's constant. DTIC

TIME-RESOLVED SHOCK COMPRESSION OF POROUS RUTILE: WAVE DISPERSION IN POROUS SOLIDS
M. U. Anderson, R. A. Graham, and G. T. Holman 1993 4 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018848; SAND-93-0406C; CONF-930676-40) Avail: CASI HC A01/MF A01

Rutile (TiO2) samples at 60% of solid density have been shock-loaded from 0.21 to 6.1 GPa with sample thickness of 4 mm and studied with the PVDF piezoelectric polymer stress-rate gauge. The technique uses a copper capsule to contain the sample which has PVDF gauge packages in direct contact with front and rear surfaces. A precise measure is made of the compressive stress wave velocity through the sample, as well as the input and propagated shock stress. Initial density is known from sample preparation, and the amount of shock-compression is calculated from the measurement of shock velocity and input stress. Shock states and re-shock states are measured. Observed data are consistent with previously published high pressure data. It is observed that rutile has a 'crush strength' near 6 GPa. Propagated stress-pulse rise times vary from 234 to 916 nsec. Propagated stress-pulse rise times of shock-compressed HMX, 2Al + Fe2O3, 3Ni + Al, and 5Ti + 3Si are presented. DOE

FINITE ELEMENT MESH GENERATION AND ANALYSIS OF SOLDER JOINTS FOR FATIGUE LIFE PREDICTIONS Final Report, 1 Jul. 1991 - 30 Jun. 1993
Nasser H. Paydar, Yihong Tong, Hasan U. Akay, and William Boehmer 30 Aug. 1993 177 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0187)
(AD-A271329; ARO-29042.1-MS) Avail: CASI HC A09

Tools for fatigue life prediction of solder joints are developed. This report consists of two parts. In part One, the creep and plastic deformations stored in a solder joint are calculated by implementing appropriate plastic and creep constitutive models in a nonlinear finite element program. The calculated damage in each cycle is then related to the life of the material using two failure criteria: strain-life and energy-partitioning. The importance of parameters affecting the fatigue life of solders are evaluated. In part Two, the finite element analysis is combined with x-ray and laser imaging systems, from which real solder joint geometries can be constructed. The approaches presented herein provides a useful tool in the design and manufacturing of surface-mount assemblies. DTIC

A BENCHMARK STUDY OF 2D AND 3D FINITE ELEMENT CALCULATIONS SIMULATING DYNAMIC PULSE BUCKLING TESTS OF CYLINDRICAL SHELLS UNDER AXIAL IMPACT
E. L. Hoffman and D. J. Ammerman 1993 6 p Presented at the 12th Biennial Conference for the International Association for Structural Mechanics in Reactor Technology (SMIRT 12), Stuttgart, Germany, 16-26 Aug. 1993
(Contract DE-AC04-76DP-00789)
(DE93-018859; SAND-93-0641C; CONF-930803-16) Avail: CASI HC A02/MF A01

A series of tests investigating dynamic pulse buckling of a cylindrical shell under axial impact is compared to several finite element simulations of the event. The purpose of the study is to compare the performance of the various analysis codes and element types with respect to a problem which is applicable to radioactive material transport packages, and ultimately to develop a benchmark problem to qualify finite element analysis codes for the transport package design industry. (DE93-018831; SAND-93-0397C; CONF-930676-38) Avail: CASI HC A01/MF A01

We have used PVDF gauges to determine time-resolved stresses resulting from interaction between hypervelocity-impact-generated debris clouds and various target gauge blocks. Debris clouds were generated from three different impact configurations: (1) steel spheres impacting steel bumper sheets at 4.5 to 6.0 km/s, (2) aluminum inhibited shaped-charge jets impacting aluminum bumper sheets at 11.4 km/s, and (3) titanium disks impacting titanium bumper sheets at 7.6 to 10.1 km/s. Additional data were collected from the various experiments using flash X-ray radiography, pulsed laser photography, impact flash measurements, time-resolved strain gauge measurements, and velocity interferometry (VISAR). Data from these various techniques are in general agreement with one another and with hydrocode predictions, and provide a quantitative and comprehensive picture of impact-generated debris clouds. DURABILITY PREDICTIONS FOR ADHESIVELY BONDED JOINTS IN HUMID ENVIRONMENTS Final Report, 15 Jan. 1990 - 14 Jul. 1993
G. J. Rodin and K. M. Liechti 29 Sep. 1993 3 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-90-G-0003)
(AD-A271177; EMRL-93-10; ARO-27315.3-EG) Avail: CASI HC A01

The research objective of this study was to develop an understanding of the cohesive failure of adhesively bonded joints under load in aggressive environments. Such an understanding could then be used to predict the durability of adhesively bonded joints in humid environments. The problem was to have been approached by first examining the diffusion kinetics and then modeling the deformation and failure behavior as a function temperature and moisture. Although only one adhesive was to have been considered in the study, the first adhesive had to be abandoned mid-way through the program (after its diffusion characteristics had been studied) when creep deformation experiments revealed an unacceptable degree of scatter due to random shear banding. After some development, a suitable second adhesive was found, but there was not enough time to completely characterize its diffusion, deformation, and failure behavior as a function of temperature and moisture. In the analytical portion of the project, finite element analyses were conducted to optimize various specimens employed in the experimental program. In addition, several thermo-mechanical models for rate-dependent materials with sensitivity to hydrostatic pressure were explored. An extended Prager Drucker plasticity model reproduced the data obtained to date. DTIC

THE p-VERSION OF THE FINITE ELEMENT METHOD IN INCREMENTAL ELASTO-PLASTIC ANALYSIS
Stefan M. Holzer and Zohar Yosibash Dec. 1993 33 p
(Contract NAG9-622; F49620-93-1-0173)
(NASA-CR-194707; NAS 1.26:194707; WU/CCM-93/4) Avail: CASI HC A03/MF A01

Whereas the higher-order versions of the finite elements method (the p- and hp-version) are fairly well established as highly efficient methods for monitoring and controlling the discretization error in linear problems, little has been done to exploit their benefits in elasto-plastic structural analysis. Aspects of incremental elasto-plastic finite element analysis which are particularly amenable to improvements by the p-version is discussed. These theoretical considerations are supported by several numerical experiments. First, an example for which an analytical solution is available is studied. It is demonstrated that the p-version performs very well even in cycles of elasto-plastic loading and unloading, not only as compared to the traditional h-version but also in respect to the exact solution. Finally, an example of considerable practical importance - the analysis of a cold-worked lug - is presented which demonstrates how the modeling tools offered by higher-order finite element techniques can contribute to an improved approximation of practical problems. Two projects are summarized in this report. The first project is entitled 'Stiffener Crippling Initiated by Delamination', and the second is entitled 'Pressure Pillowing of an Orthogonally Stiffened Cylindrical Shell.' The objective of the first project is to develop a computational model of the stiffener specimens that includes the capability to predict the interlaminar stress response at the flange free edge in postbuckling. The objectives of the second project are to analyze the concentration of interacting loads at the stiffener intersection and to study the pillowing of the skin.

Effective computational simulation procedures are described for modeling the inherent multi-disciplinary interactions which govern the accurate response of propulsion systems. Results are presented for propulsion system responses including multi-disciplinary coupling effects using coupled multi-discipline thermal, structural, and acoustic tailoring; an integrated system of multi-disciplinary simulators; coupled material behavior/fabrication process tailoring; sensitivities using a probabilistic simulator; and coupled materials, structures, fracture, and probabilistic behavior simulator. The results demonstrate that superior designs can be achieved if the analysis/tailoring methods account for the multi-disciplinary coupling effects. The coupling across disciplines can be used to develop an integrated coupled multi-discipline numerical propulsion system simulator.

QUANTIFICATION OF UNCERTAINTIES IN THE PERFORMANCE OF SMART COMPOSITE STRUCTURES
Michael C. Shiao (Sverdrup Technology, Inc., Brook Park, OH.) and Christos C. Chamis Oct. 1993 21 p Presented at the 34th Structures, Structural Dynamics, and Materials Conference, La Jolla, CA, 19-21 Apr. 1993; cosponsored by AIAA, ASME, AHS, and ASC
(RTOP 210-02-12)
(NASA-TM-106335; E-8102; NAS 1.15:106335) Avail: CASI HC A03/MF A01

A composite wing with spars, bulkheads, and built-in control devices is evaluated using a method for the probabilistic assessment of smart composite structures. Structural responses (such as change in angle of attack, vertical displacements, and stresses in regular plies with traditional materials and in control plies with mixed traditional and actuation materials) are probabilistically assessed to quantify their respective scatter. Probabilistic sensitivity factors are computed to identify those parameters that have a significant influence on a specific structural response. Results show that the uncertainties in the responses of smart composite structures can be quantified. Responses such as structural deformation, ply stresses, frequencies, and buckling loads in the presence of defects can be reliably controlled to satisfy specified design requirements. Author

NUMERICAL SIMULATIONS OF HYPERVELOCITY IMPACT EXPERIMENTS INVOLVING SINGLE WHIPPLE BUMPER SHIELDS Final Report, 8 Jun. - 3 Sep. 1992
David F. Medina and Scott R. Maethner Oct. 1993 67 p
(AF Proj. SNL-O)
(AD-A272123; PL-TR-93-1027) Avail: CASI HC A04/MF A01

Well-controlled hypervelocity impact experiments, conducted in support of the Space Station Shielding program, were numerically modeled using two sophisticated hydrocodes, the multidimensional hydrodynamics code (CTH), and the Smoothed Particle Hydrodynamics code (SPH). The experiments simulated the impact of space debris on single shields and single Whipple bumper shield plate configurations. Impact velocities on the order of 10 km/s were applied to gram-sized flier lates and spherical projectiles that struck thin aluminum, titanium, and steel plates. Computational predictions of the debris cloud dynamics and plate damage for these experiments were analyzed and correlated with the data obtained from pulsed laser photographs and high-speed x-ray photography. Computational results of both hydrocodes were compared to each other. DTIC

TWO-DIMENSIONAL FINITE ELEMENT ANALYSIS OF POROUS MEDIA AT MULTIKILOBAR STRESS LEVELS Final Report
Stephen A. Akers Sep. 1993 105 p
(AD-A271540; WES/TR/SL-93-16) Avail: CASI HC A06/MF A02

A finite element (FE) code was developed to verify laboratory test results or to predict unavailable laboratory test data for porous media loaded to multikilobar stress levels. The FE code simulates quasi-static, axisymmetric, laboratory mechanical property tests, i.e., the laboratory tests are analyzed as boundary value problems. The code calculates strains, total and effective stresses, and pore fluid pressures for fully and partially saturated porous media. The time-dependent flow of the pore fluid is also calculated. An elastic-plastic strain-hardening cap model calculates the time-independent skeletal responses of the porous solids. This enables the code to model nonlinear irreversible stress-strain behavior and shear-induced volume changes. Fluid and solid compressibilities were incorporated into the code, and partially saturated materials were simulated with a 'homogenized' compressible pore fluid. Solutions for several verification problems are given as proof that the program works correctly, and numerical simulations of limestone behavior under drained and undrained boundary conditions are also presented. ADAPTATION OF MODEL PARAMETERS OF A RAIL MODEL AT MEASURED RAIL COMPLIANCES [ANPASSUNG DER MODELLPARAMETER EINES GLEISMODELLS AN GEMESSENE GLEISREZEPTANZEN]
B. Ripke Jan. 1992 37 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ILR-Mitt-274(1992); ETN-93-94174) Avail: CASI HC A03

A method for calculation of unknown parameters of a rail model is presented. Measurements were carried out on a test rail of a locomotive factory by means of pulse excitation. Accelerations of the rail head in the vertical and laterial directions were measured with an accelerometer and dilatations were measured as a function of rail flexion with a piezo film. Input and transfer compliances were measured. The obtained data were controlled by means of a fast Fourier transformation analyzer and recorded on magnetic tapes. A model was developed with the finite element method by considering the rail as a Timoshinko beam. Stiffness and damping of bulkhead and tiebar were obtained. A variable threshold mass was introduced for model adaptation to the experiment results in low frequency area. ESA

DYNAMIC RESPONSE OF MULTIPHASE POROUS MEDIA Final Report, 1 Feb. 1989 - 31 May 1993
Daniel E. Chitty, Scott E. Blouin, Kwang J. Kim, and Alan F. Rauch 16 Jun. 1993 236 p
(Contract F49620-89-C-0037)
(AD-A272915; ARA-5535-3; AFOSR-93-0838TR) Avail: CASI HC A11/MF A03

This report presents the results of a three-year theoretical and experimental investigation of the response of multiphase porous media to strong dynamic loadings. A material element model was developed to automate the determination of parameter values for multiphase material models and to predict the response of saturated porous materials to arbitrary stress, strain and fluid flow boundary conditions. Laboratory tests to measure fluid flow through porous media were conducted over a wide range of pressure gradients in granular materials and porous rock. The results of those tests were used to develop a unified fluid friction model. A laboratory apparatus was constructed for the purpose of studying wave propagation through saturated porous media. A suite of dynamic tests was performed on a porous stainless steel specimen, and the results of those tests were compared with detailed multiphase numerical simulations. The simulations were in excellent agreement with the laboratory measurements. With guidance from simulations, it was possible to identify in the test data, the wave of the second kind. This disturbance, which propagates at a speed significantly lower than the compressional wave, appears to be associated with a surge of pore fluid within the porous skeleton, and has previously only been predicted by analysis. ADHESIVE BONDED JOINT WITH IMPROVED CYCLIC FATIGUE LIFE FOR ALUMINA-CERAMIC CYLINDERS AND HEMISPHERES: FOURTH GENERATION HOUSINGS Final Report
J. D. Stachiw Aug. 1993 118 p
(AD-A273061; NCCOSC/RDT/E-TR-1587) Avail: CASI HC A06/MF A02

A series of 20-inch-diameter monocoque cylinders of 94-percent alumina-ceramic were pressure tested to determine their structural performance under repeated pressurizations to 9,000 psi external design pressure when their ends are encapsulated in epoxy-filled Mod 1 titanium or aluminum end caps. Naval Ocean Systems Center (NOSC) Type Mod 1 titanium end caps provided an order-of-magnitude improvement in cyclic fatigue life for the ceramic cylinders over previously tested Mod 0 end caps. The cyclic fatigue life of 20-inch OD by 18.63-inch ID by 30-inch L by 0.685-inch t ceramic cylinders with 0.5-inch weight/displacement ratio, the ends of which were encapsulated with epoxy adhesive in Mod 1 titanium end caps, exceeded 400 cycles to 9,000 psi that generated inside the cylinder compressive membrane stresses of 136,000 psi magnitude in hoop and 68,000 psi in axial direction. At these stress levels, the shell of the monocoque cylinder can tolerate imperfections in the shape of spherical 0.063-inch) and oblong cavities (less than or equal to 0.063-inch by less than or equal to 0.187-inch) located below, or on the shell surface, provided that they are at least two inches away from the ends. The payload-carrying

ability of 94-percent alumina-ceramic monocoque cylinders with above dimensions is approximately four-times larger than rib-stiffened titanium cylinders with the same external dimensions and pressure rating. DTIC

NUMERICAL MODELING OF A PROPAGATING CRACK M.S. Thesis
Clifford Christy Jun. 1993 58 p
(AD-A272604) Avail: CASI HC A04/MF A01

In the numerical modeling of the crack propagation in dynamic fracture using stationary elements, a discrete and sudden release of node at the crack tip creates spurious oscillation in the kinetic and strain energy values. In order to reduce the oscillation, a moving node element was utilized. This element can model a continuous crack tip movement more closely. The moving node element is compatible with surrounding regular isoparametric elements and no remeshing is required during the crack propagation. In addition, two different central difference schemes were compared and their results were almost the same. DTIC

EXPERIMENTAL AND NUMERICAL STUDIES OF HIGH-VELOCITY IMPACT FRAGMENTATION
M. E. Kipp, D. E. Grady, and J. W. Swegle Aug. 1993 130 p
(Contract DE-AC04-76DP-00789)
(DE93-040205; SAND-93-0773) Avail: CASI HC A07/MF A02

Developments are reported in both experimental and numerical capabilities for characterizing the debris spray produced in penetration events. A series of high-velocity experiments specifically designed to examine the fragmentation of the projectile during impact were performed. High-strength, well-characterized steel spheres (6.35 mm diameter) were launched with a two-stage light-gas gun to velocities in the range of 3 to 5 km/s. Normal impact with PMMA plates, thicknesses of 0.6 to 11 mm, applied impulsive loads of various amplitudes and durations to the steel sphere. Multiple flash radiography diagnostics and recovery techniques were used to assess size, velocity, trajectory, and statistics of the impact-induced fragment debris. Damage modes to the primary target plate (plastic) and to a secondary target plate (aluminum) were also evaluated. Dynamic fragmentation theories, based on energy-balance principles, were used to evaluate local material deformation and fracture state information from CTH, a three-dimensional Eulerian solid dynamics shock wave propagation code. The local fragment characterization of the material defines a weighted fragment size distribution, and the sum of these distributions provides a composite particle size distribution for the steel sphere. The calculated axial and radial velocity changes agree well with experimental data, and the calculated fragment sizes are in qualitative agreement with the radiographic data. A secondary effort involved the experimental and computational analyses of normal and oblique copper ball impacts on steel target plates. High-resolution radiography and witness plate diagnostics provided impact motion and statistical fragment size data. CTH simulations were performed to test computational models and numerical methods.

RESULTS OF THE SECOND ROUND ROBIN ON OPENING-LOAD MEASUREMENT CONDUCTED BY ASTM TASK GROUP E24.04.04 ON CRACK CLOSURE MEASUREMENT AND ANALYSIS
E. P. Phillips Nov. 1993 38 p
(RTOP 50-63-50-04)
(NASA-TM-109032; NAS 1.15:109032) Avail: CASI HC A03/MF A01

A second experimental Round Robin on the measurement of the crack opening load in fatigue crack growth tests has been completed by the ASTM Task Group E24.04.04 on Crack Closure Measurement and Analysis. Fourteen laboratories participated in the testing of aluminum alloy compact tension specimens. Opening-load measurements were made at three crack lengths during constant Delta K, constant stress ratio tests by most of the participants. Four participants made opening-load measurements during threshold tests. All opening-load measurements were based on the analysis of specimens compliance behavior, where the displacement/strain was measured either at the crack mouth or the mid-height back face location. The Round Robin data were analyzed for opening load using two non-subjective analysis methods: the compliance offset and the correlation coefficient methods. The scatter in the opening load results was significantly reduced when some of the results were excluded from the analysis population based on an accept/reject criterion for raw data quality. The compliance offset and correlation coefficient opening load analysis methods produced similar results for data populations that had been screened to eliminate poor quality data. Author (revised)

A general computational simulation methodology for an integrated probabilistic assessment of composite structures is discussed and demonstrated using aircraft fuselage (stiffened composite cylindrical shell) structures with rectangular cutouts. The computational simulation was performed for the probabilistic assessment of the structural behavior including buckling loads, vibration frequencies, global displacements, and local stresses. The scatter in the structural response is simulated based on the inherent uncertainties in the primitive (independent random) variables at the fiber matrix constituent, ply, laminate, and structural scales that describe the composite structures. The effect of uncertainties due to fabrication process variables such as fiber volume ratio, void volume ratio, ply orientation, and ply thickness is also included. The methodology has been embedded in the computer code IPACS (Integrated Probabilistic Assessment of Composite Structures). In addition to the simulated scatter, the IPACS code also calculates the sensitivity of the composite structural behavior to all the primitive variables that influence the structural behavior. This information is useful for assessing reliability and providing guidance for improvement. The results from the probabilistic assessment for the composite structure with rectangular cutouts indicate that the uncertainty in the longitudinal ply stress is mainly caused by the uncertainty in the laminate thickness, and the large overlap of the scatter in the first four buckling loads implies that the buckling mode shape for a specific buckling load can be either of the four modes. SURFACE AND SUBSURFACE DEFECT DETECTION IN Si3N4 COMPONENTS BY LASER SCATTERING
J. S. Steckenrider and W. A. Ellingson 1993 23 p Presented at the 20th Annual Review of Progress in Quantitative Nondestructive Evaluation, Brunswick, ME, 1-6 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE93-040829; ANL/ET/CP-79613; CONF-9308167-2) Avail: CASI HC A03

Lifetimes of Si3N4 components that experience contact fatigue (e.g., bearings) are affected by defects (voids, inclusions, etc.) at or near the surface (less than 200 microns). An optical technique was developed for rapid detection and quantification of defects in both surface and subsurfaces, as well as characterization of subsurface microstructure. This laser scattering technique was applied to various Si3N4 component shapes. Polarization techniques were used to independently analyze surface and subsurface material, and surface defects such as Vickers indent markings were detected at 10-50 microns; subsurface defects were also detected (simulated voids at depths up to 100 microns below surface). Subsurface microstructure (locally high porosity, grain orientation variations) has been characterized.

IMPROVEMENTS TO A METHOD FOR THE GEOMETRICALLY NONLINEAR ANALYSIS OF COMPRESSIVELY LOADED STIFFENED COMPOSITE PANELS Final Technical Report, Feb. 1991 - Dec. 1993
Frederick Stoll 1993 128 p
(Grant NAG1-1215)
(NASA-CR-194715; NAS 1.26:194715) Avail: CASI HC A07/MF A02

The NLPAN computer code uses a finite-strip approach to the analysis of thin-walled prismatic composite structures such as stiffened panels. The code can model in-plane axial loading, transverse pressure loading, and constant through-the-thickness thermal loading, and can account for shape imperfections. The NLPAN code represents an attempt to extend the buckling analysis of the VIPASA computer code into the geometrically nonlinear regime. Buckling mode shapes generated using VIPASA are used in NLPAN as global functions for representing displacements in the nonlinear regime. While the NLPAN analysis is approximate in nature, it is computationally economical in comparison with finite-element analysis, and is thus suitable for use in preliminary design and design optimization. A comprehensive description of the theoretical approach of NLPAN is provided. A discussion of some operational considerations for the NLPAN code is included. NLPAN is applied to several test problems in order to demonstrate new program capabilities, and to assess the accuracy of the code in modeling various types of loading and response. User instructions for the NLPAN computer program are provided, including a detailed description of the input requirements and example input files for two stiffened-panel configurations.

A THERMODYNAMIC THEORY OF DYNAMIC FRAGMENTATION
Ching H. Yew (Texas Univ., Austin.) and P. A. Taylor 1993 10 p Presented at the Annual Winter Meeting of the American Society of Mechanical Engineers, New Orleans, LA, 28 Nov. - 3 Dec. 1993
(Contract DE-AC04-76DP-00789)
(DE93-019066; SAND-93-0887C; CONF-931121-18) Avail: CASI HC A02/MF A01

We present a theory of dynamic fragmentation of brittle materials based on thermodynamic arguments. We recover the expressions for average fragment size and number as originally derived by Grady. We extend the previous work by obtaining descriptions of fragment size distribution and compressibility change due to the fragmentation process. The size distribution is assumed to be proportional to the spectral power of the strain history and a sample distribution is presented for a fragmentation process corresponding to a constant rate strain history. The description of compressibility change should be useful in computational studies of fragmentation. These results should provide insight into the process of fragmentation of brittle materials from hypervelocity impact. DOE

A VIBRATION MODEL FOR CENTRIFUGAL CONTACTORS
R. A. Leonard, M. O. Wasserman, and D. G. Wygmans Nov. 1992 84 p
(Contract W-31-109-eng-38)
(DE93-040645; ANL-92/40) Avail: CASI HC A05/MF A01

Using the transfer matrix method, we created the Excel worksheet 'Beam' for analyzing vibrations in centrifugal contactors. With this worksheet, a user can calculate the first natural frequency of the motor/rotor system for a centrifugal contactor. We determined a typical value for the bearing stiffness (k(sub B)) of a motor after measuring the k(sub B) value for three different motors. The k(sub B) value is an important parameter in this model, but it is not normally available for motors. The assumptions that we made in creating the Beam worksheet were verified by comparing the calculated results with those from a VAX computer program, BEAM IV. The Beam worksheet was applied to several contactor designs for which we have experimental data and found to work well. DOE

MODAL COMBINATION IN RESPONSE SPECTRUM MODAL DYNAMIC ANALYSIS
C. R. Hammond and M. K. Singhal 1993 5 p Presented at the 4th Energy Natural Phenomena Hazards Mitigation Conference, Atlanta, GA, 19-22 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000339; CONF-9310102-21) Avail: CASI HC A01/MF A01

UCRL-15910 does not give explicit requirements for combining the values of the response of individual modes in a response spectrum modal dynamic analysis. Since UCRL-15910 references ASE 4-86, modal combination methods given in ASCE 4-86 are described in this paper. Efficient use of typical dynamic analysis computer programs while complying with ASCE 4-86 is also described. DOE

BENEFITS OF THREAD ROLLING PROCESS TO THE STRESS CORROSION CRACKING AND FATIGUE RESISTANCE OF HIGH STRENGTH FASTENERS
A. R. Kephart and S. Z. Hayden May 1993 14 p Presented at the 6th International Symposium on Environmental Degradation of Materials in Nuclear Power Systems: Water Reactors, San Diego, CA, 3-5 Aug. 1993
(Contract DE-AC12-76SN-00052)
(DE93-040438; KAPL-4759; CONF-930825-5) Avail: CASI HC A03/MF A01

Stress corrosion cracking (SCC) behavior of cut (machined) vice thread rolled Alloy X-750 and Alloy 625 fasteners in a simulated high temperature primary water environment has been evaluated. SCC testing at 360 and 338 C included 157 small and 40 large 60 degree thread studs. Thread rolled fasteners had improved resistance relative to cut fasteners. Tests of fatigue resistance in air at room temperature and both air and primary water at 315 C were conducted on smaller studs with both cut and rolled threads. Results showed rolled threads can have significantly improved fatigue lives over those of cut threads in both air and primary water. Fasteners produced by two different thread rolling methods, in-feed (radial) and through-feed (axial), revealed similar SCC initiation test results. Testing of thread rolled fasteners revealed no significant SCC or fatigue growth of rolling induced thread crest laps typical of the thread rolling process. While fatigue resistance differed between the two rolled thread supplier's studs, neither of the suppliers studs showed SCC initiation at exposure times beyond that of cut threads with SCC. In contrast to rolling at room temperature, warm rolled (427 C) threads showed no improvement over cut threads in terms of fatigue resistance. The observed improved SCC and fatigue performance of rolled threads is postulated to be due to interactive factors, including beneficial residual stresses in critically stressed thread root region, reduction of plastic strains during loading and formation of favorable microstructure. RESPONSE STATISTICS OF SHELL STRUCTURES WITH GEOMETRICAL AND MATERIAL NONLINEARITIES, VOLUME 1 Ph.D. Thesis
Meilan Liu 1993 681 p
(ISBN-0-315-84006-4; CTN-94-60960) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A series of hybrid strain-based three-node flat triangular shell elements is developed for structural analyses. For linear analyses, the Hellinger Reissner (H-R) variational principle is employed. The elements are obtained by combining a triangular bending element and a plane stress element. For nonlinear analysis, the updated Lagrangian formulation and the incremental H-R variational principle are applied. The incremental second Piola Kirchhoff stress and the incremental Washizu strain are chosen as incremental stress and strain measures. Material nonlinearity is of the elastoplastic type with isotropic hardening. In all cases, explicit expressions for the stiffness and consistent mass matrices are obtained. The various shell structures studied show that the element formulations are accurate, effective, flexible, and applicable to thin to moderately thick shells with geometrical and material nonlinearities. In parallel, the stochastic central difference (SCD) method is applied to determine response statistics of general structures. The SCD method is extended to include a relatively general nonstationary random excitation comprising deterministic and stochastic components. It is applied to compute the random responses of general nonlinear shell structures. Numerical results employing the proposed methodologies are presented and their effectiveness is addressed.

Avail: CASI HC A03/MF A03

The purpose is to provide an end-user's perspective on the state of the art in life prediction and failure analysis by focusing on subsonic transport fuselage issues being addressed in the NASA/Boeing Advanced Technology Composite Aircraft Structure (ATCAS) contract and a related task-order contract. First, some discrepancies between the ATCAS tension-fracture test database and classical prediction methods is discussed, followed by an overview of material modeling work aimed at explaining some of these discrepancies. Finally, analysis efforts associated with a pressure-box test fixture are addressed, as an illustration of modeling complexities required to model and interpret tests. Author (revised)

Avail: CASI HC A03/MF A03

The ideas associated with the subsequent viewgraphs are summarized. The primary motivation behind this presentation is to observe that certain macroscopic, microscopic, and submicroscopic phenomena are being understood that have basic influence on understanding the durability and high temperature sensitivity of polymers and polymer-based composites. This understanding covers important issues of long term stability with respect to residual stresses and deformations which can have very deleterious effects on structures used for long periods of time as a result of the heat-involving manufacturing process. Beyond this, important progress is being made in understanding the nonlinear material response of polymers in the fracture context, because the nonlinear mechanics of the material at the tip of a crack, either propagating or ready to do so, is being understood with increasing precision. A THERMODYNAMIC ANALYSIS OF PROPAGATING SUBCRITICAL CRACKS WITH COHESIVE ZONES

David H. Allen *In* NASA. Langley Research Center, Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 53-81 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

The results of the so-called energetic approach to fracture with particular attention to the issue of energy dissipation due to crack propagation are applied to the case of a crack with cohesive zone. The thermodynamic admissibility of subcritical crack growth (SCG) is discussed together with some hypotheses that lead to the derivation of SCG laws. A two-phase cohesive zone model for discontinuous crack growth is presented and its thermodynamics analyzed, followed by an example of its possible application. Author

BRIEF SUMMARY OF THE EVOLUTION OF HIGH-TEMPERATURE CREEP-FATIGUE LIFE PREDICTION MODELS FOR CRACK INITIATION

Gary R. Halford *In* NASA. Langley Research Center, Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 121-150 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

The evolution of high-temperature, creep-fatigue, life-prediction methods used for cyclic crack initiation is traced from inception in the late 1940's. The methods reviewed are material models as opposed to structural life prediction models. Material life models are used by both structural durability analysts and by material scientists. The latter use micromechanistic models as guidance to improve a material's crack initiation resistance. Nearly one hundred approaches and their variations have been proposed to date. This proliferation poses a problem in deciding which method is most appropriate for a given application. Approaches were identified as being combinations of thirteen different classifications. This review is intended to aid both developers and users of high-temperature fatigue life prediction methods by providing a background from which choices can be made. The need for high-temperature, fatigue-life prediction methods followed immediately on the heels of the development of large, costly, high-technology industrial and aerospace equipment immediately following the second world war. Major advances were made in the design and manufacture of high-temperature, high-pressure boilers and steam turbines, nuclear reactors, high-temperature forming dies, high-performance poppet valves, aeronautical gas turbine engines, reusable rocket engines, etc. These advances could no longer be accomplished simply by trial and error using the 'build-em and bust-em' approach. Development lead times were too great and costs too prohibitive to retain such an approach. Analytic assessments of anticipated performance, cost, and durability were introduced to cut costs and shorten lead times. The analytic tools were quite primitive at first and out of necessity evolved in parallel with hardware development. After forty years more descriptive, more accurate, and more efficient analytic tools are being developed. These include thermal-structural finite element and boundary element analyses, advanced constitutive stress-strain-temperature-time relations, and creep-fatigue-environmental models for crack initiation and propagation. The high-temperature durability methods that have evolved for calculating high-temperature fatigue crack initiation lives of structural engineering materials are addressed. Only a few of the methods were refined to the point of being directly useable in design. Recently, two of the methods were transcribed into computer software for use with personal computers. LIFE ASSESSMENT OF STRUCTURAL COMPONENTS USING INELASTIC FINITE ELEMENT ANALYSES

Vinod K. Arya (Toledo Univ., OH.) and Gary R. Halford *In* NASA. Langley Research Center, Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 151-163 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

The need for enhanced and improved performance of structural components subject to severe cyclic thermal/mechanical loadings, such as in the aerospace industry, requires development of appropriate solution technologies involving time-dependent inelastic analyses. Such analyses

are mandatory to predict local stress-strain response and to assess more accurately the cyclic life time of structural components. The NASA-Lewis Research Center is cognizant of this need. As a result of concerted efforts at Lewis during the last few years, several such finite element solution technologies (in conjunction with the finite element program MARC) were developed and successfully applied to numerous uniaxial and multiaxial problems. These solution technologies, although developed for use with MARC program, are general in nature and can easily be extended for adaptation with other finite element programs such as ABAQUS, ANSYS, etc. The description and results obtained from two such inelastic finite element solution technologies are presented. The first employs a classical (non-unified) creep-plasticity model. An application of this technology is presented for a hypersonic inlet cowl-lip problem. The second of these technologies uses a unified creep-plasticity model put forth by Freed. The structural component for which this finite element solution technology is illustrated, is a cylindrical rocket engine thrust chamber. The advantages of employing a viscoplastic model for nonlinear time-dependent structural analyses are demonstrated. The life analyses for cowl-lip and cylindrical thrust chambers are presented. These analyses are conducted by using the stress-strain response of these components obtained from the corresponding finite element analyses. Author (revised)

RECENT ADVANCES IN COMPUTATIONAL STRUCTURAL RELIABILITY ANALYSIS METHODS **c38**
Ben H. Thacker, Y.-T. Wu, Harry R. Millwater, Tony Y. Torng, and David S. Riha *In* NASA. Langley Research Center, Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 185-203 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

The goal of structural reliability analysis is to determine the probability that the structure will adequately perform its intended function when operating under the given environmental conditions. Thus, the notion of reliability admits the possibility of failure. Given the fact that many different modes of failure are usually possible, achievement of this goal is a formidable task, especially for large, complex structural systems. The traditional (deterministic) design methodology attempts to assure reliability by the application of safety factors and conservative assumptions. However, the safety factor approach lacks a quantitative basis in that the level of reliability is never known and usually results in overly conservative designs because of compounding conservatisms. Furthermore, problem parameters that control the reliability are not identified, nor their importance evaluated. A summary of recent advances in computational structural reliability assessment is presented. A significant level of activity in the research and development community was seen recently, much of which was directed towards the prediction of failure probabilities for single mode failures. The focus is to present some early results and demonstrations of advanced reliability methods applied to structural system problems. This includes structures that can fail as a result of multiple component failures (e.g., a redundant truss), or structural components that may fail due to multiple interacting failure modes (e.g., excessive deflection, resonate vibration, or creep rupture). From these results, some observations and recommendations are made with regard to future research needs. Author (revised)

ANALYSIS OF THERMAL MECHANICAL FATIGUE IN TITANIUM MATRIX COMPOSITES
W. Steven Johnson and Massoud Mirdamadi *In its* Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 225-238 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

Titanium metal matrix composites are being evaluated for structural applications on advanced hypersonic vehicles. These composites are reinforced with ceramic fibers such as silicon carbide, SCS-6. This combination of matrix and fiber results in a high stiffness, high strength composite that has good retention of properties even at elevated temperatures. However, significant thermal stresses are developed within the composite between the fiber and the matrix due to the difference in their respective coefficients of thermal expansion. In addition to the internal stresses that are generated due to thermal cycling, the overall laminate will be subjected to considerable mechanical loads during the thermal cycling. In order to develop life prediction methodology, one must be able to predict the stresses and strains that occur in the composite's constituents during the complex loading. Thus the purpose is to describe such an analytical tool, VISCOPLY. Author (revised)

TIME-DEPENDENT RELIABILITY ANALYSIS OF CERAMIC ENGINE COMPONENTS **c38**
Noel N. Nemeth *In* NASA. Langley Research Center, Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 239-269 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

The computer program CARES/LIFE calculates the time-dependent reliability of monolithic ceramic components subjected to thermomechanical and/or proof test loading. This program is an extension of the CARES (Ceramics Analysis and Reliability Evaluation of Structures) computer program. CARES/LIFE accounts for the phenomenon of subcritical crack growth (SCG) by utilizing either the power or Paris law relations. The two-parameter Weibull cumulative distribution function is used to characterize the variation in component strength. The effects of multiaxial stresses are modeled using either the principle of independent action (PIA), the Weibull normal stress averaging method (NSA), or the Batdorf theory. Inert strength and fatigue parameters are estimated from rupture strength data of naturally flawed specimens loaded in static, dynamic, or cyclic fatigue. Two example problems demonstrating proof testing and fatigue parameter estimation are given. Author (revised)

DELAMINATION, DURABILITY, AND DAMAGE TOLERANCE OF LAMINATED COMPOSITE MATERIALS **c24**
T. Kevin OBrien *In its* Computational Methods for Failure Analysis and Life Prediction Oct. 1993 p 311-322 (For primary document see N94-22608 05-39)
Avail: CASI HC A03/MF A03

Durability and damage tolerance may have different connotations to people from different industries and with different backgrounds. Damage tolerance always refers to a safety of flight issue where the structure must be able to sustain design limit loads in the presence of damage and return to base safely. Durability, on the other hand, is an economic issue where the structure must be able to survive a certain life under load before the initiation of observable damage. Delamination is typically the observable damage mechanism that is of concern for durability, and the growth and accumulation of delaminations through the laminate thickness is often the sequence of events that leads to failure and the loss of structural integrity. Avail: CASI HC A03/MF A03

Commercial transport aircraft operating in the United States are certified by the Federal Aviation Authority to be damage tolerant. On 28 April 1988, Aloha Airlines Flight 243, a Boeing 727-200 airplane, suffered an explosive decompression of the fuselage but landed safely. This event provides very strong justification for the damage tolerant design criteria. The likely cause of the explosive decompression was the linkup of numerous small fatigue cracks that initiated at adjacent fastener holes in the lap splice joint at the side of the body. Actually, the design should have limited the damage size to less than two frame spacings (about 40 inches), but this type of 'multi-site damage' was not originally taken into account. This cracking pattern developed only in the high-time airplanes (many flights). After discovery in the fleet, a stringent inspection program using eddy current techniques was inaugurated to discover these cracks before they linked up. Because of concerns about safety and the maintenance burden, the lap-splice joints of these high-time airplanes are being modified to remove cracks and prevent new cracking; newer designs account for 'multi-site damage'. The Biological and Environmental Research (BER) Program of OHER has two main missions: (1) to develop the knowledge base necessary to identify, understand, and anticipate the long-term health and environmental consequences of energy use and development; and (2) to utilize the Department's unique scientific and technological capabilities to solve major scientific problems in medicine, biology, and the environment. These missions reflect a commitment to develop the beneficial uses of advanced energy technologies while at the same time assuring that any potentially adverse health and environmental impacts of the Nation's energy policies are fully identified and understood. The BER Program includes research in the following areas: atmospheric, marine, and terrestrial processes, including the linkage between the use in greenhouse gases, carbon dioxide, and regional and global climate change; in molecular and subcellular mechanisms underlying human somatic and genetic processes and their responses to energy-related environmental toxicants; in nuclear medicine, structural biology, the human genome, measurement sciences and instrumentation; and other areas that require the unique capabilities of the Department's laboratory system. The principal areas of research are Health Research and Environmental Research. DOE

GLOBAL AND REGIONAL COMPARATIVE PERFORMANCE OF LINEAR AND NONLINEAR SATELLITE MULTICHANNEL SEA SURFACE TEMPERATURE ALGORITHMS Final Report

Douglas A. May Sep. 1993 36 p

(NRL Proj. 0101)

(AD-A270475; NRL/MR/7240-93-7049) Avail: CASI HC A03/MF A01

This report summarizes investigations conducted at the Naval Research Laboratory on the accuracy of advanced very high resolution radiometer (AVHRR) satellite sea surface temperature (SST) retrieval techniques. Investigations focused on linear and nonlinear AVHRR atmospheric correction algorithms and their comparative performance relative to global drifting buoy in situ SST observations. Satellite retrievals were matched to drifting buoy SST's within two hours and ten kilometers from January to December 1990. Emphasis was placed on the bias and root-mean-square difference (rmsd) statistical accuracy of each algorithm for various global regions, atmospheric conditions, and seasonal time periods. Results demonstrate that the nonlinear sea surface temperature (NLSST) algorithm provides consistently better bias and rmsd accuracy statistics relative to the other algorithms tested. Given these results, it is recommended that global satellite SST retrieval processing should utilize the NLSST algorithm for operational retrieval generation. Recommendations are also provided for future algorithms. DTIC

MODELING OF INTERACTIONS BETWEEN BIOSPHERE AND ATMOSPHERE ON THE GLOBAL SCALE Final Report

Ferdinand Baer and Y. Mintz 20 Aug. 1990 4 p

(Grant NAG5-383)

(NASA-CR-193423; NAS 1.26:193423) Avail: CASI HC A01/MF A01

Simulations of weather and climate with general circulation models show that the circulation and rainfall are sensitive to the transfers of radiation, sensible heat, water vapor, and momentum across the atmosphere land surface interface. Because, in nature, these transfers depend in large measure on the morphological and physiological characteristics of the surface vegetation, an interactive biosphere is needed for GCM's. The simple model of the biosphere (SiB) that the authors have constructed is based on the recognized difference between ground cover vegetation (grasses and other herbaceous plants) and canopy vegetation (trees and shrubs), where the latter act like elevated blocks of porous material which efficiently extract momentum from the air that flows through them; by a large number of multiple reflections enhance the absorption of the incident solar radiation; when the canopy is wet, act like well ventilated psychrometers which extract sensible heat from the air and produce a negative Bowen ratio; and, in all of these ways, behave differently from ground cover vegetation. The complete set of governing equations of SiB, whereby the various allowable combinations of trees, ground covers, and bare ground, in interaction with the atmosphere, determine all of the vegetation dependent transfers at the land surface, have been presented and described. THE FUTURE OF REMOTE SENSING FROM SPACE: CIVILIAN SATELLITE SYSTEMS AND APPLICATIONS

Jul. 1993 216 p Original contains color illustrations

(OTA-ISC-558; ISBN-0-16-041884-4) Avail: CASI HC A10/MF A03; SOD HC

Over the past decade, the United States and other countries have increasingly turned to satellite remote sensing to gather data about the state of earth's atmosphere, land, and oceans. Satellite systems provide the vantage point and coverage necessary to study our planet as an integrated, interactive physical and biological system. In particular, the data they provide, combined with data from surface and aircraft-based instruments, should help scientists monitor, understand, and ultimately predict the long term effects of global change. This report, the first of three in a broad OTA assessment of earth observation systems, examines issues related to the development and operation of publicly funded U.S. and foreign civilian remote sensing systems. It also explores the military and intelligence use of data gathered by civilian satellites. In addition, the report examines the outlook for privately funded and operated remote sensing systems. Despite the established utility of remote sensing technology in a wide variety of applications, the state of the U.S. economy and the burden of an increasing Federal deficit will force NASA, NOAA, and DoD to seek ways to reduce the costs of remote sensing systems. This report observes that maximizing the return on the U.S. investment in satellite remote sensing will require the Federal Government to develop a flexible, long-term interagency plan that would guarantee the routine collection of high-quality measurements of the atmosphere, oceans, and land over decades. Such a plan would assign the part each agency plays in gathering data on global change, including scientifically critical observations from aircraft- and ground-based platforms, as well as from space-based platforms. It would also develop appropriate mechanisms for archiving, integrating, and distributing data from many different sources for research and other purposes. Finally, it would assign to the private sector increasing responsibility for collecting and archiving remotely sensed data. Derived from text

AN EXPERT SYSTEM SHELL FOR INFERRING VEGETATION CHARACTERISTICS Final Report, Mar. - Nov. 1993

P. Ann Harrison and Patrick R. Harrison Nov. 1993 145 p The Lisp and KEE code for this work is available on a Sun cartridge tape

(Contract NAS5-30127; RTOP 462-61-14)

(NASA-CR-194569; NAS 1.26:194569; C931033-U-2R00) Avail: CASI HC A07/MF A02

The NASA VEGetation Workbench (VEG) is a knowledge based system that infers vegetation characteristics from reflectance data. VEG is described in detail in several references. The first generation version of VEG was extended. In the first year of this contract, an interface to a file of unknown cover type data was constructed. An interface that allowed the results of VEG to be written to a file was also implemented. A learning system that learned class descriptions from a data base of historical cover type data and then used the learned class descriptions to classify an unknown sample was built. This system had an interface that integrated it into the rest of VEG. The VEG subgoal PROPORTION.GROUND.COVER was completed and a number of additional techniques that inferred the proportion ground cover of a sample were implemented. This work was previously described. The work carried out in the second year of the contract is described. The historical cover type database was removed from VEG and stored as a series of flat files that are external to VEG. An interface to the files was provided. The framework and interface for two new VEG subgoals that estimate the atmospheric effect on reflectance data were built. A new interface that allows the scientist to add techniques to VEG without assistance from the developer was designed and implemented. A prototype Help System that allows the user to get more information about each screen in the VEG interface was also added to VEG. Author (revised)

MEASUREMENT OF EVAPOTRANSPIRATION WITH COMBINED REFLECTIVE AND THERMAL INFRARED RADIANCE OBSERVATIONS Final Report

Allen S. Hope 1993 150 p

(Grant NAG5-911)

(NASA-CR-194802; NAS 1.26:194802) Avail: CASI HC A07/MF A02

The broad goal of the research summarized in this report was 'To facilitate the evaluation of regional evapotranspiration (ET) through the combined use of solar reflective and thermal infrared radiance observations.' The specific objectives stated by Goward and Hope (1986) were to: (1) investigate the nature of the relationship between surface temperature (T(sub S)) and the normalized difference vegetation index (NDVI) and develop an understanding of this relationship in terms of energy exchange processes, particularly latent flux heat (LE); (2) develop procedures to estimate large area LE using combined T(sub S) and NDVI observations obtained from AVHRR data; and (3) determine whether measurements derived from satellite observations relate directly to measurements made at the surface or from aircraft platforms. Both empirical and modeling studies were used to develop an understanding of the T(sub S)-NDVI relationship. Most of the modeling was based on the Tergra model as originally proposed by Goward. This

model, and modified versions developed in this project, simulates the flows of water and energy in the soil-plant-atmosphere system using meteorological, soil and vegetation inputs. Model outputs are the diurnal course of soil moisture, T(sub S), LE and the other individual components of the surface energy balance. Derived from text

Remote Sensing provides one or a few of the many data required in GIS/LIS for evaluation of various types of land capabilities, such as land capability for urban land use, agricultural use, and for forestry use. In northeastern Brazil, satellite data such as SPOT HRV and Landsat-TM were utilized to provide land use information for the semi-arid areas of the region. The present investigation was conducted over an area of approximately 700 Km(sup 2) in northeastern Brazil at JAICO and its environs located in the sul of the Piaui state. A Raster based Computer Mapping System-ERDAS (Earth Resources Data Analysis System) for a hybridized unsupervised-supervised classification (Maximum Likelihood) approach was used in order to extract 17 land use/land cover classes at the Level 2 of Anderson Classification. These classes were recoded in order to detect the 11 soil association classes in accordance with the Brazilian and USDA Systems which were then recoded into 9 land capability units using the Brazilian and American Systems. Finally, three maps were derived for the objectives of regional planning under this investigation: (1) Land use/Land cover map; (2) Soil Associations map; and (3) Land Capability Units map. This system is used to store information of various properties of land development for regional planning in NE Brazil. Comparison of digital interpretation with reference information indicated that digital interpretation, closely resembled field observation and the overall classification accuracy was observed 84.7 percent. Paragominas region, at Eastern Para, is one of the oldest colonization centers of Amazonia. The objective was the change detection of land use in colonization settlements of that country, focusing forest cover, using LANDSAT satellite imagery. The methodology adopted included the examination of NDVI (normalized difference vegetation index), supervisioned classification (minimum distance), and the change detection technique. Results evidenced rainforest regeneration at Uraim Colony, a settlement that showed successful socio-economic characteristics. Author (revised)

A linear mixing model was applied to coarse spatial resolution data from the NOAA Advanced Very High Resolution Radiometer. The reflective component of the 3.55 - 3.93 microns channel was extracted and used with the two reflective channels 0.58 - 0.68 microns and 0.725 - 1.1 microns to run a Constraine Least Squares model to generate vegetation, soil, and shade fraction images for an area in the Western region of Brazil. The Landsat Thematic Mapper data covering the Emas National park region was used for estimating the spectral response of the mixture components and for evaluating the mixing model results. The fraction images were compared with an unsupervised classification derived from Landsat TM data acquired on the same day. The relationship between the fraction images and normalized difference vegetation index images show the potential of the unmixing techniques when using coarse resolution data for global studies. An introduction to some of the potential uses of hyperspectral data for ecosystem analysis is presented. The examples given are derived from a digital dataset acquired over a sub-boreal forest in central Maine in 1990 by the NASA-JPL Airborne Visible and Infrared Imaging Spectrometer (AVIRIS) instrument gathers data from 400 to 2500 nm in 224 channels at bandwidths of approximately 10 nm. As a preview to the uses of the hyperspectral data, several products from this dataset were extracted. They range from the traditional false color composite made from simulated Thematic Mapper bands and the well known normalized difference vegetation index to much more exotic products such as fractions of vegetation, soil and shade based on linear spectral mixing models and estimates of the leaf water content at the landscape level derived using spectrum-matching techniques. Our research and that of many others indicates that the hyperspectral datasets carry much important information which is only beginning to be understood. This analysis gives an initial indication of the utility of hyperspectral data. Much work still remains to be done in algorithm development and in understanding the physics behind the complex information signal carried in the hyperspectral datasets. This work must be carried out to provide the fullest science support for high spectral resolution data to be acquired by many of the instruments to be launched as part of the Earth Observing System program in the mid-1990's. Satellite platforms have provided a methodology for regional and global remote sensing of aerosols. New systems will significantly improve that capability during the EOS era; however, the voluminous 20 year record of satellite data has produced only regional snapshots of aerosol loading and have not yielded a data base of the optical properties of those aerosols which are fundamental to our understanding of their influence on climate change. The prospect of fully understanding the properties of the aerosols with respect to climate change is small without validation and augmentation by ancillary ground based observations. Sun photometry was demonstrated to be an effective tool for ground based measurements of aerosol optical properties from fire emissions. Newer technology has expanded routine sun photometer measurements to spectral observations of solar aureole and almucantar allowing retrievals of size distribution, scattering phase function, and refractive index. A series of such observations were made in Brazil's Amazon basin from a network of six simultaneously recording instruments deployed in Sep. 1992. The instruments were located in areas removed from local aerosol sources such that sites are representative of regional aerosol conditions. The overall network was designed to cover the counter clockwise tropospheric circulation of the Amazon Basin. Spectral measurements of sun, aureole and sky data for retrieval of aerosol optical thickness, particle size distribution, and scattering phase function as well as measurements of precipitable water were made during noncloudy conditions. PREDICTING LANDSAT MSS ENDMEMBER SIGNATURES FROM CORRESPONDING HIGHER RESOLUTION TM FRACTION IMAGES
Yosio E. Shimabukuro (Instituto de Pesquisas Espaciais, Sao Jose dos Campos, Brazil.) and James A. Smith *In* INPE, The 7th Brazilian Remote Sensing Symposium, Volume 3 1993 p 117-128 (For primary document see N94-20960 05-43)
Avail: CASI HC A03/MF A04

The approach to predicting Landsat Multispectral Scanner System (MSS) endmember signatures from fraction images derived from high resolution Landsat Thematic Mapper (TM) data is presented. The purpose, conducted in the Mogi-Guacu study site located in Sao Paulo State, Brazil, was to determine if information derived from a mixture model applied to higher resolution TM data could serve as ground truth for the lower resolution MSS sensor. The Constrained Least Squares (CLS) method was used to generate vegetation, soil, and shade fraction images from the TM data. The resulting images were then used to estimate the endmember spectral response for MSS data by regressing each MSS spectral channel against the corresponding proportion values estimated for the same resolution cells from the TM mixture model. The evaluation of the predicted signatures was performed by comparing the corresponding fraction images derived from both the MSS and TM data acquired on 14 Sep. 1986. The techniques serves as a potential tool for integrating information in global studies where remote sensors with different spectral and spatial resolutions were used.

ON THE ORIGIN AND EVOLUTION OF CIRCULAR FORMS OBSERVED IN REMOTE SENSING IMAGES OF THE RIO DE JANEIRO STATE, BRAZIL
Andre Calixto Vieira, Antonio Carlos J. deCastro, and Edgar Hans Brauer *In* INPE, The 7th Brazilian Remote Sensing Symposium, Volume 3 1993 p 385-394 (For primary document see N94-20960 05-43)
Avail: CASI HC A02/MF A04

The origin and evolution of circular, semi-circular, and stick-like forms identified in a selected area at the southwestern portion of the Rio de Janeiro State, Brazil, is related. Some of these 'morphological anomalies' were previously described either as igneous intrusions or as plutonic domes. A Tertiary tectonics of NW-SE compressional stress is known to be responsible for NE-SW movement of extense blocks. The tangential component of this movement caused the horizontal displacement and partition of pegmatites along the host-rock foliation. Conjugating the NW-SE compressional stress that acted upon the superior crust, with the tangential displacement of blocks situated over the underground, it is possible to suggest a model for the origin of the forms above mentioned. Remote sensing images of a target area were selected to identify the relation of several features with the morphological, structural, and drainage anomalies. Author (revised)

As part of the SAREX'92 (South American Radar Experiment), the Tapajos study site, located in Para State, Brazil was imaged by the Canada Center for Remote Sensing (CCRS) Convair 580 SAR system using a C-band frequency in HH and VV polarization and 3 different imaging modes (nadir, narrow, and wide swath). A preliminary analysis of this dataset is presented. The wide swath C-band HH polarized image was enlarged to 1:100,000 in a photographic form for manual interpretation. This was compared with a vegetation map produced primarily from Landsat Thematic Mapper (TM) data and with single-band and color composite images derived from a decomposition analysis of TM data. The Synthetic Aperture Radar (SAR) image shows well the topography and drainage network defining the different geomorphological units, and canopy texture differences which appear to be related to the size and maturity of the forest canopy. Areas of recent clearing of the primary forest can also be identified on the SAR image. The SAR system appears to be a source of information for monitoring tropical forest which is complementary to the Landsat Thematic Mapper.

DROUGHT EARLY WARNING SYSTEM FOR CROP PRODUCTION
William T. Liu *In* INPE, The 7th Brazilian Remote Sensing Symposium, Volume 4 1993 p 160-164 (For primary document see N94-20965 05-43)
Avail: CASI HC A01/MF A04

A new drought early warning system similar to the system developed by NOAA/NESDIS is suggested for implantation in Brazil. The proposed drought early warning system is based on three subsystems: agroclimatic index, satellite assessment, and crop yield forecast subsystems. Each subsystem contains several well developed assessment tools, derived from various data sources. Assessment tools produced by the drought early warning system include: NOAA satellite products such as vegetation index and vegetation condition index maps; vegetation index time-series and color-coded images; agroclimatic indices such as crop water use maps; crop risk index tables and maps; and crop yield forecast models including agrometeorological models, crop growth models, and vegetation index models. Short and long term weather forecast information should be incorporated in producing an assessment report. A geographic information system, which analyzes various data sources by overlaying, integrating and cross-checking between different assessment tools for consistency and convergence of information, should be used to produce a synthesized quantitative report.

During the past decade there has been a sharply increasing interest and need in obtaining environmental information related to the aquatic domain. The ability to receive serial information about current or recent weather, hydrological or environmental (quality) conditions, in a timely and reliable fashion is now recognized as the basis for any modern environmental monitoring system, whether the data are used for the protection of the environment, or to minimize the negative impact of extreme environmental conditions on the day-to-day safety of communities. Because the reliability of receiving such data via conventional telephone lines is often affected by the same adverse weather or environmental conditions being reported by the system, a modern system based on telemetry via satellite, that is, a system where the environment is remotely sensed, should be considered among the most reliable and desirable systems. The development of project SIMA, an integrated system for monitoring the aquatic environment, is presented. Because SIMA is based on the ARGOS system aboard the polar orbiting NOAA satellites, SIMA has no global limits for its 19+ million sq km regional coverage. The objective of this project is to design and develop a prototype system that can be used to monitor conditions in a coastal region where the possibility of oil spills exists, or in inland waters such as reservoirs and lakes, where the system can monitor changes in environmental parameters that may indicate the onset of floods, pollutants entering a reservoir, and so forth. Details of how SIMA functions, as well as its capabilties, are presented.

The remote sensing programs of Brazil and Canada originated in late 1960's through participation in NASA's LANDSAT program. National governments of both countries have supported the development of remote sensing activities. Both countries have shared common interests in developing this technology in terms of large geographic areas and strong interests in natural resources exploration and management. Despite these similarities, the situation in the two countries are quite different today. There are between 3000 and 5000 remote sensing users in Canada. The majority are in the private sector. While there are approximately 3000 remote sensing users in Brazil, 85 percent of the users are in the public sector. Just few private companies are involved with remote sensing technology in Brazil, of these just two companies are 100 percent involved. There are many sectors of the economy that could benefit from remote sensing information; however, this large market remains undeveloped. One may conclude that more needs to be done if remote sensing technology is to be transferred successfully from the public to the private sector in Brazil. The purpose is to gain a better understanding of the evolution of remote sensing activities in Brazil and Canada over the past 25 years in order to further technology transfer/diffusion activities within the Brazilian context.

RAPID ESTIMATES OF CROP PRODUCTION USING REMOTE SENSING: EUROPEAN EXPERIENCE
Helene deBoissezon and M. Sharman (Joint Research Centre of the European Communities, Ispra, Italy.) *In* INPE, The 7th Brazilian Remote Sensing Symposium, Volume 4 1993 p 442-449 (For primary document see N94-20965 05-43)
Avail: CASI HC A02/MF A04

A technique in which high-resolution satellite imagery from SPOT and the Thematic Mapper is used in an operational way to provide rapid estimates of annual changes in area and production of various important crops in

Europe is described. The results, produced throughout the crop year, are transmitted to the Directorate General of Agriculture of the Commission of the European Communities and to the Statistical Office of European Communities, where they help to provide precise and up-to-date information on agricultural production. The agricultural information must be delivered rapidly in order to be of use. The Joint Research Center, which is responsible for this work, has set a target of 10 days from the date of acquisition to the date of delivery of the information. This tight schedule, and the number of sites (53) which are to be monitored, requires a novel and industrial approach to the image analysis. The operational implications of these requirements are examined and the fact that the Action 4 system is now fully operational is demonstrated. Author (revised)

USING NDVI/AVHRR DATA FOR CROP MONITORING AND FORECASTING IN SOUTH ITALY
Paolo Rossini *In* INPE, The 7th Brazilian Remote Sensing Symposium, Volume 4 1993 p 458-463 (For primary document see N94-20965 05-43)
Avail: CASI HC A02/MF A04

Crop monitoring, and in particular yield estimate and forecast, is considered very important for those Boards in charge to monitor agrarian season. Remote Sensing for its features and potentiality can contribute to these tasks in some new and interesting ways. The potential use of Advanced Very High Resolution Radiometer (AVHRR)/Normalized Difference Vegetation Index (NDVI) data from NOAA satellites for crop monitoring in South Italy within an interregional agrometeorological project is investigated. Over 1600 images in LAC format are processed from 1986 to date. Using previous results on NDVI correlation with plant photosynthetic capacity and efficiency during wheat Grain Filling Period Duration (GFPD), a simple linear regression model was derived for wheat yield estimate and forecast for each South Italy Agricultural Region. Estimated and forecasted values are compared with official ISTAT data. Author (revised)

INFORMATION EXTRACTION FOR MULTISPECTRAL IMAGES USING RADIATION INTERACTION MODELS [INFORMATIE-EXTRACTIE UIT MULTISPECTRALE BEELDEN MET BEHULP VAN STRALINGSINTERACTIEMODELLEN]
W. Verhoef (National Aerospace Lab., Amsterdam, Netherlands.) Jul. 1992 49 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(BCRS-90-22; NLR-TP-90243-U; ISBN-9-05-411052-X; ETN-93-93312)
Avail: CASI HC A03

The possibilities of extraction of quantitative information from multispectral images of overgrown areas were investigated using radiation interaction models. Taking example by LANDSAT Thematic Mapper images it is shown that it is possible to construct reflection images and to extract reflection spectra of objects, using calibration and atmospheric correction. The usage of a vegetation reflection model in the interpretation of reflection spectra was started. ESA

OCEAN MAPPING USING SATELLITE RADAR ALTIMETRY [OCEANEN IN KAART DOOR HOOGTEMETING MET SATELLIETRADAR]
Jun. 1992 4 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-93470) Avail: CASI HC A01

Sea surface altimetry using satellite radar is applied for the study of ocean topography and ocean circulation. The American satellite GEOS-3, Seasat and Geosat, and the European satellites ERS-1 and TOPEX/POSEIDON were used. Radar altimetry and ocean circulation data with very high precision were obtained and used as input for models, resulting in a better insight in the sea bottom topography and the Earth mantle structure under the oceans, which is important for science, offshore industry, and military use. A better knowledge of large ocean circulations and vortices is important for the study of environment and climate. ESA

SNOW COVER MEASUREMENTS AND AREAL ASSESSMENT OF PRECIPITATION AND SOIL MOISTURE
B. Sevruk, ed. 1992 299 p
(WMO-749; OHR-35; ISBN-9-26-310749-1; ETN-93-94841) Copyright
Avail: CASI MF A03; print copy available from WMO, Geneva, Switzerland

Recent developments in the field of areal estimation of precipitation, snow cover characteristics, and soil moisture, including remote sensing, are summarized. Numerous references and examples are provided along with annexes containing more detailed information on the following: snowfall estimation using radar, statistical estimation of snow cover fields, and semivariograms. The roles of precipitation, snow cover, and soil moisture in the water balance and for hydrological modeling are outlined. Some relevant physical properties of precipitation and soil required to understand the main topic are discussed. Methods of point and area measurement, in particular remote sensing techniques, are described. The general principles of the transformation of point values to mean areal values and the problem of representative point data are discussed. Emphasis is laid on the accuracy aspects of areal estimates, including systematic errors of point measurements and random errors originating from the local effects of measuring site and network density. The actual error of areal estimates can either be evaluated empirically by using the tables and diagrams enclosed or derived more objectively by using statistical analysis of spatial variability of particular hydrological variables. REMOTE SENSING FOR HYDROLOGY PROGRESS AND PROSPECTS
R. Kuttinen 1992 71 p
(WMO-773; OHR-36; ISBN-9-26-310773-9; ETN-93-94842) Copyright
Avail: CASI MF A01; print copy available from WMO, Geneva, Switzerland

The capability of satellite and aircraft based remote sensing techniques to meet the requirements of the World Meteorological Organization for operational hydrology programs at the present time and in the foreseeable future is discussed. The focus is on the application of remote sensing techniques to estimate hydrological variables and only limited information is provided on the technical aspects of the satellites, the sensors, and the data transmission and data interpretation devices. The observational requirements for operational hydrology are discussed. The technical aspects of sensors and data dissemination systems as well as the economic and practical aspects of remote sensing are considered. The applications for the measurement of precipitation, soil moisture and groundwater, evapotranspiration (including lake evaporation and evaporation from bare soils), snow, ice and frost, and surface water parameters are discussed. The use of remote sensing for the mapping of basic characteristics such as basin area, topography, soil types, vegetation, land use, and water courses is considered. Remotely sensed hydrological variables as inputs to hydrological models are discussed together with future trends in this field. Three appendices containing the observational requirements for operational hydrology and the assessed capability of remote sensing satellites and sensors relevant until 1995 as well as a list of LANDSAT and SPOT data distributors are provided. DATA FORMAT STANDARDS FOR CIVILIAN REMOTE SENSING SATELLITES
May 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-192920) Avail: CASI HC A03

The Office of Technology Assessment (OTA) was asked by the Senate Armed Services Committee to investigate the plethora of formats for remotely sensed Earth data. At a workshop held on 2 Oct. 1992, participants discussed the pros and cons of standardizing formats for remote-sensed data, the question of how many different standards are needed, with what else should remote-sensed data be compatible, and who should set the standards. It was clear from the workshop that data from different sources are largely provided in different formats and on different media. Moreover, formats, media, and recording hardware for the same system have often changed over time leading to situations where old data is virtually inaccessible. Creating order out of the current chaos will be a very difficult proposition and is likely to cause problems for many suppliers and users of data. Nevertheless, the payoff for doing so may be sufficiently great to warrant a major effort in that direction. NTIS

DETECTING TOPOGRAPHICAL REGIONS IN DIGITAL TERRAIN MAPS

Sabrina Sestito, Simon Goss, and Terry Caelli Aug. 1993 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272889; ARL-TR-53; DODA-AR-008-387) Avail: CASI HC A03

This report describes an application of Clustering and Differential Geometry to the characterization of digital terrain maps by different surface types and critical regions. Of particular interest is the determination of specific terrain types, where they occur, and describing them in ways which are invariant to viewing position. The development of robust and efficient segmentation and associated region characterization procedures is reported. Good results have been obtained for characterizing digital terrain maps. This work supports the development of techniques for generating optimal flight paths. DTIC

PUBLICATION OF SCIENCE DATA ON CD-ROM: A GUIDE AND EXAMPLE
Gary Angelici and J. W. Skiles (Johnson Controls World Services, Cape Canaveral, FL.) Nov. 1993 62 p Sponsored by NASA. Washington (Contract NAS2-13210)
(NASA-CR-4560; A-94024; NAS 1.26:4560) Avail: CASI HC A04/MF A01

CD-ROM (Compact Disk-Read Only Memory) is becoming the standard media not only in audio recording, but also in the publication of data and information accessible on many computer platforms. Little has been written about the complicated process involved in creating easy-to-use, high quality, and useful CD-ROM's containing scientific data. This document is a manual designed to aid those who are responsible for the publication of scientific data on CD-ROM. All aspects and steps of the procedure are covered, from feasibility assessment through disk design, data preparation, disc mastering, and CD-ROM distribution. General advice and actual examples are based on lessons learned from the publication of scientific data for an interdisciplinary field experiment. Appendices include actual files from a CD-ROM, a purchase request for CD-ROM mastering services, and the disk art for the first disk published for the project. Author

URBAN APPLICATIONS OF SATELLITE REMOTE SENSING AND GIS ANALYSIS
B. Paulsson 1992 73 p
(PB93-202174; DP-9) Copyright Avail: Issuing Activity

The report serves as a practical guide to show how satellite remote sensing can be a useful source of urban management information and to demonstrate the benefits of geographical analysis of available data. It focuses on operational applications in cities in developing countries, based on a comprehensive review of recent reports and illustrated by experience from case studies and operational projects. It does not attempt to cover all possible urban applications of GIS technology or serve as a detailed manual for all possible applications of satellite remote sensing. Rather, it offers an introduction to the technologies, available range of products, and various methods of analysis offered by satellite remote sensing. NTIS

INFLUENCE OF GEOID MODEL UNCERTAINTY ON THE DETERMINATION OF OCEAN CIRCULATION WITH SATELLITE ALTIMETRY
Ina A. Elema Feb. 1993 109 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-219301) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report contains the study of the inaccuracy in the determination of ocean circulation by satellite altimetry due to geoid errors. Chapter 2 gives a summary of the usefulness and applications of satellite altimetry. Chapter 3 gives some background of oceanography. The different types of ocean variations are described. In chapter 4, three methods to determine the geostrophic flow are described: the hydrographic method, the absolute method, and the integrated approach. The disadvantages and advantages of the methods are compared with each other. The problems in defining the geoid and its determination are presented in chapter 5. The accuracy of geoid models is briefly discussed. The influence of the accuracy of the earlier introduced geoid models on two test areas with varying parameters (such as maximum degree of expansion, zonals, tesserals) can be found in chapters 6 and 7. In chapter 8, conclusions from this investigation are drawn. Recommendations for further work concerning this topic are given in chapter 9. NTIS

ESTIMABILITY OF POLAR MOTION USING RANGE OBSERVATIONS TO SATELLITES
A. P. Kap Feb. 1993 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB93-219319) Avail: CASI HC A05

The purpose of the research has been to evaluate a model that gives a relation between, on one side, a range observation between an observation station on the Earth and a satellite, and the parameters that describe the motion of the Earth and the satellite on the other side. This evaluation was aimed at the estimability of the various parameters, possible rank deficiencies, and strong correlations, with special attention to the polar motion of the Earth. Contents include: Use of reference frames; Dynamics of a rigid body; Rotation of the Earth; Representation of the satellite orbit using Hill equations; The influence of the Earth's flattening on the satellite orbit; A model for the range observation; Testing of the model using singular value decomposition; Conclusions and recommendations. DATA MANAGEMENT FOR INTERDISCIPLINARY FIELD EXPERIMENTS: OTTER PROJECT SUPPORT
Gary Angelici, Lidia Popovici, and J. W. Skiles (Johnson Controls World Services, Cape Canaveral, FL.) Nov. 1993 23 p
(Contract NAS2-13210)
(NASA-CR-4559; A-94023; NAS 1.26:4559) Avail: CASI HC A03/MF A01

The ability of investigators of an interdisciplinary science project to properly manage the data that are collected during the experiment is critical to the effective conduct of science. When the project becomes large, possibly including several scenes of large-format remotely sensed imagery shared by many investigators requiring several services, the data management effort can involve extensive staff and computerized data inventories. The OTTER (Oregon Transect Ecosystem Research) project was supported by the PLDS (Pilot Land Data System) with several data management services, such as data inventory, certification, and publication. After a brief description of these services, experiences in providing them are compared with earlier data management efforts and some conclusions regarding data management in support of interdisciplinary science are discussed. In addition to providing these services, a major goal of this data management capability was to adopt characteristics of a pro-active attitude, such as flexibility and responsiveness, believed to be crucial for the effective conduct of active, interdisciplinary science. These are also itemized and compared with previous data management support activities. Identifying and improving these services and characteristics can lead to the design and implementation of optimal data management support capabilities, which can result in higher quality science and data products from future interdisciplinary field experiments. CHROMATICITY ANALYSIS OF LANDSAT MULTISPECTRAL SCANNER AND THEMATIC MAPPER IMAGERY OF CHILKO LAKE, BRITISH COLUMBIA, USING A THEORETICAL OPTICAL WATER QUALITY MODEL Ph.D. Thesis
Elizabeth Ann Gallie Jun. 1990 283 p
(ISBN-0-315-63832-X; CTN-94-60889) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Chromaticity analysis of LANDSAT multispectral scanner (MSS) imagery of Chilko Lake, British Columbia, reveals a locus whose shape has not been previously reported. To examine the cause of this and to gain knowledge of chromaticity analysis for MSS and Thematic Mapper (TM) data, an optical water quality model has been used. The model is composed of a reflectance model (R-model), an interface model, and an atmospheric model. The R-model was calibrated for Chilko Lake by determining the specific backscattering and absorption spectra for suspended minerals (SM), chlorophyll (C), and yellow substance (YS). The model reproduces the observed locus shape and indicates that it is primarily a function of SM. If brightness is used in combination with the chromaticity coordinate X, the model predicts that C and YS can be differentiated from SM at most SM concentrations. Furthermore, haze and wind gradients can be distinguished from the lower limb of MSS X-Y plots. Simulated chromaticity results were compared with results from actual images for which ground truth had been collected. Qualitative predictions regarding haze and water quality patchiness were confirmed. Modelling error is thought to originate in atmospheric assumptions which are not met. The study concludes that the model is qualitatively correct and that the use of brightness improves chromaticity analysis. Author (CISTI)

STAR-1 SAR ROAD EXTRACTION USING TEXTURE ANALYSIS AND MATHEMATICAL MORPHOLOGY Ph.D. Thesis
Elly Rasdiani Sudibjo Sep. 1992 172 p
(ISBN-0-315-83255-X; CTN-94-60939) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Synthetic aperture radar (SAR) images are becoming an important source of mapping information in many countries, especially where cloud cover is a major problem. Radar imagery is often used with other remote sensing imagery since these data are often the only source of mapping information. To correlate and use the data from different sensors, the data must be registered to each other, such as by using a linear feature as the registration feature. A methodology of road extraction was developed by a sequential procedure of smoothing, texture analysis, and mathematical morphology. The methodology was tested on a 250 by 250 pixel data set from a mountainous area covering about 1.5 by 1.5 km. Smoothing or noise reduction was applied before the texture analysis using six different filtering techniques, of which two were applicable for producing a filtered image. Texture analysis was investigated and an empirical evaluation was applied to four texture methods. For extracting the road network, thresholds were applied to texture values. To reconstruct the road network, a mathematical morphology dilation was implemented, using different sizes and patterns of structuring elements. With the proper choice of thresholds, roads could be detected and extracted, and the reconstruction procedures were able to connect the road network. Author (CISTI)

Testimony was submitted to the Senate on the environmental impacts of accelerated research and development of hydrogen-based energy systems. The advantages of hydrogen in transportation systems, in fuel cells for electric vehicles and power plants, and in energy storage from off-peak electricity production are described. The largest barrier to using hydrogen in the transportation sector is the on-board storage of enough fuel to provide an adequate driving range in an urban environment. Production methods and costs are also discussed. The authors believe a coordinated demonstration program with U.S. industry is needed to develop the best technologies for hydrogen-fueled vehicles. HIGH EFFICIENCY EPITAXIAL OPTICAL REFLECTOR SOLAR CELLS
P. D. Dapkus and S. G. Hummel Aug. 1993 49 p Prepared in cooperation with Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-017115; NREL/TP-451-5591) Avail: CASI HC A03/MF A01

This report describes work to test the feasibility of a new solar cell concept -- the epitaxial optical reflector (EOR) solar cell. This cell concept alters current designs for high efficiency cells by changing the optical absorption efficiency of single cells. The change is introduced by the use an epitaxial multilayer reflector as an integral part of the cell to increase the optical path length of certain wavelengths of light in the cell. These changes are expected to increase the open circuit voltage at which power is extracted from the cell. The program is designed to test the feasibility of the use of a broadband epitaxial multilayer reflector grown as an integral part of the device structure to reflect the near-band-edge light back through the device for a second absorption pass. This second pass allows the design of a solar cell with a thinner base and the use of the epitaxial reflector as a heterojunction carrier-reflecting barrier at the rear of the device. The thinner cell design and altered carrier profile that results from the light- and carrier-reflecting barrier will decrease the carrier concentration gradient and increase the open circuit voltage. The program is structured to have three tasks: solar cell and reflector modeling, materials growth and optimization, and solar cell fabrication and characterization. DOE

DEVELOPMENT OF HIGH-EFFICIENCY CdTe SOLAR CELLS
A. Rohatgi, H. C. Chou, A. K. Bhat, and S. Kamra Aug. 1993 52 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-018206; NREL/TP-451-5650) Avail: CASI HC A04/MF A01

This report describes work to improve the basic understanding of the loss mechanisms in thin-film CdS/CdTe solar cells and to improve their efficiency by characterizing the properties of the films as well as the finished devices. To accomplish this, solar cells were fabricated on glass/SnO2CdS substrates by metal-organic chemical vapor deposition (MOCVD) growth of CdTe films and evaporation of Cu/Au contacts. The substrates were provided by Solarex Corporation and were recently grown in house on glass/SnO2 substrates using solution growth. Rapid thermal processing (RTP), still a relatively new technology with growing applications in the semiconductor industry, is being investigated in this program as an alternative to the conventional post-growth furnace annealing of the CdS/CdTe films. Consistent with the long-term goals of cost-effective, large-scale terrestrial applications of photovoltaics, we also made some preliminary investigations of a solution growth technique for depositing CdTe films. ABSORPTION HEAT PUMP FOR SPACE APPLICATIONS Final Report
Tuan Nguyen, William E. Simon, Gopinath R. Warrier, and Woranun Woramontri Dec. 1993 152 p
(Grant NAG9-613)
(NASA-CR-194693; NAS 1.26:194693) Avail: CASI HC A08/MF A02

In the first part, the performance of the Absorption Heat Pump (AHP) with water-sulfuric acid and water-magnesium chloride as two new refrigerant-absorbent fluid pairs was investigated. A model was proposed for the analysis of the new working pairs in a heat pump system, subject to different temperature lifts. Computer codes were developed to calculate the Coefficient of Performance (COP) of the system with the thermodynamic properties of the working fluids obtained from the literature. The study shows the potential of water-sulfuric acid as a satisfactory replacement for water-lithium bromide in the targeted temperature range. The performance of the AHP using water-magnesium chloride as refrigerant-absorbent pair does not compare well with those obtained using water-lithium bromide. The second part concentrated on the design and testing of a simple ElectroHydrodynamic (EHD) Pump. A theoretical design model based on continuum electromechanics was analyzed to predict the performance characteristics of the EHD pump to circulate the fluid in the absorption heat pump. A numerical method of solving the governing equations was established to predict the velocity profile, pressure - flow rate relationship and efficiency of the pump. The predicted operational characteristics of the EHD pump is comparable to that of turbomachinery hardware; however, the overall efficiency of the electromagnetic pump is much lower. An experimental investigation to verify the numerical results was conducted. The pressure - flow rate performance characteristics and overall efficiency of the pump obtained experimentally agree well with the theoretical model. Author (revised)

ENERGY STORAGE AND CONVERSION IN SOLID HYDROGEN Final Report, 19 Sep. 1988 - 19 Mar. 1992
James R. Gaines and C. A. Vause Aug. 1993 27 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04611-88-K-0048)
(AD-A271439; PL-TR-92-3019; AD-E201667) Avail: CASI HC A03

The trapping of unpaired atoms of hydrogen (H) in a solid hydrogen matrix (Hsub2) increases the energy available for propulsion applications, i.e. the specific impulse. The incremental increase in stored energy depends on the metastable atomic hydrogen concentration. To maintain a large atomic hydrogen concentration, recombination of atoms into molecules must be understood and suppressed. It was the purpose of this research to study both theoretical and experimental approaches to creating large atomic hydrogen concentrations. The theoretical considerations have lead to analytic procedures for calculating the atom diffusion times and the atomic recombination coefficients from statistical mechanics. The experimental studies have yielded numerical estimates of the atom density in solid tritium based on measurements of the ortho to para tritium conversion rate. The atom density expressed as a concentration approaches 1% near K. Such large atom densities lead to very unusual thermal response when the temperature of the host solid matrix is increased, resulting from the rapid recombination of the trapped atoms. In practice, this response provides a method of retrieving the stored energy from the host solid. DTIC

FABRICATION OF STABLE LARGE-AREA THIN-FILM CdTe PHOTOVOLTAIC MODULES
J. F. Nolan and P. V. Meyers Aug. 1993 24 p Prepared in cooperation with Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-018204; NREL/TP-413-5740) Avail: CASI HC A03/MF A01

This report highlights the progress made by Solar Cells, Inc. (SCI), in its program to produce 60-cm x 120-cm solar modules based on CdTe films. During the past year, confirmed efficiency has increased to 10.4% (active area) on a 1 sq cm cell, 9.8% (aperture area) on a 64 sq cm

8-cell submodule, and 6.6% (total area) on a 7200 sq cm module. A module measured in-house had a power output of 53 W, for a total-area efficiency of 7.4%. Average efficiency of modules produced is steadily increasing and standard deviation is decreasing; in a limited run of 12 modules, results were 6.3% +/- 0.2%. Field testing has begun; a nominal 1-kW array of 24 modules was set up adjacent to SCI's facilities. Analysis indicates that present modules are limited in efficiency by shunt resistance and optical absorption losses in the glass superstrate. Loss analysis of present devices allows us to project a module efficiency of 11.8%. A third generation deposition method, atmospheric pressure elemental vapor deposition (APEVD), has been brought on-line and has produced good quality CdTe. In addition, SCI is expanding its pro-active safety, health, environmental, and disposal program dealing with issues surrounding cadmium. DOE

DEVELOPMENT OF A NUMERICAL SIMULATION MODEL FOR a-Si:H SOLAR CELLS AND APPLICATION TO THE ANALYSIS OF EXPERIMENTALLY OBTAINED SPECTRAL CHARACTERISTICS Ph.D. Thesis [DIE ENTWICKLUNG EINES NUMERISCHEN SIMULATIONSMODELLS FUER A-SI:H SOLARZELLEN UND SEINE ANWENDUNG ZUR ANALYSE EXPERIMENTELL ERMITTELTER SPEKTRALCHARAKTERISTIKEN]
Juergen Bruns 1993 134 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ETN-93-95061) Avail: CASI HC A07

Solar cells for simulating the properties of thin layer cells for a-Si:H are modeled. A numerical simulation model, based on the finite difference method, is developed assuming that the amorphous material can be described by the semiconductor physics. The components were characterized by the transport equations, which were discretized and linearized in order to obtain a matrix with a tridiagonal structure for solving the partial differential equations. Properties of amorphous silicon were taken into account for the physical description of trapping and recombination processes. The distribution of localized states in motion holes was represented with two exponential tail states and two Gaussian distribution dangling bond states. A spectral measuring apparatus was built for examining the influence of the model parameters on the solar cell electrical characteristic line. The voltage dependence of photocurrent was observed with the quantum efficiency degree curve. A dispersive transition of primary to secondary photocurrent area is found, which is different for pin and nip solar cells. Spectral response simulation for both cell types show that this transition is caused by an exchange of drift and diffusion processes, which are compensated by photocurrent extinguishing. ESA

FLUID ABSORPTION SOLAR ENERGY RECEIVER Final Report, 1 May 1991 - 15 Apr. 1993
Edward J. Bair 1993 88 p
(Grant NAG3-1014)
(NASA-CR-194688; NAS 1.26:194688) Avail: CASI HC A05/MF A01

A conventional solar dynamic system transmits solar energy to the flowing fluid of a thermodynamic cycle through structures which contain the gas and thermal energy storage material. Such a heat transfer mechanism dictates that the structure operate at a higher temperature than the fluid. This investigation reports on a fluid absorption receiver where only a part of the solar energy is transmitted to the structure. The other part is absorbed directly by the fluid. By proportioning these two heat transfer paths the energy to the structure can preheat the fluid, while the energy absorbed directly by the fluid raises the fluid to its final working temperature. The surface temperatures need not exceed the output temperature of the fluid. This makes the output temperature of the gas the maximum temperature in the system. The gas can have local maximum temperatures higher than the output working temperature. However local high temperatures are quickly equilibrated, and since the gas does not emit radiation, local high temperatures do not result in a radiative heat loss. Thermal radiation, thermal conductivity, and heat exchange with the gas all help equilibrate the surface temperature. Derived from text

POWER CONDITIONING SYSTEM MODELLING FOR NUCLEAR ELECTRIC PROPULSION Final Report
Kenneth J. Metcalf Nov. 1993 164 p
(Contract NAS3-25808; RTOP 593-72-00)
(NASA-CR-191136; NAS 1.26:191136) Avail: CASI HC A08/MF A02

NASA LeRC is currently developing a Fortran based model of a complete nuclear electric propulsion (NEP) vehicle that would be used for piloted and cargo missions to the Moon or Mars. The proposed vehicle design will use either a Brayton or K-Rankine power conversion cycle to drive a turbine coupled with a rotary alternator. Two thruster types are also being studied, ion and magnetoplasmadynamic (MPD). In support of this NEP model, Rocketdyne developed a power management and distribution (PMAD) subroutine that provides parametric outputs for selected alternator operating voltages and frequencies, thruster types, system power levels, and electronics coldplate temperatures. The end-to-end PMAD model described is based on the direct use of the alternator voltage and frequency for transmitting power to either ion or MPD thrusters. This low frequency transmission approach was compared with dc and high frequency ac designs, and determined to have the lowest mass, highest efficiency, highest reliability and lowest development costs. While its power quality is not as good as that provided by a high frequency system, it was considered adequate for both ion and MPD engine applications. The low frequency architecture will be used as the reference in future NEP PMAD studies. Author (revised)

The National Renewable Energy Laboratory (NREL) estimated that the deployment of photovoltaics (PV) in the commercial buildings sector has the potential to contribute as much as 40 gigawatts peak electrical generation capacity and displace up to 1.1 quads of primary fuel use. A significant portion of this potential exists for smaller buildings under 25,000 square feet (2,300 square meters) in size or two stories or less, providing a strong cross over potential for residential applications as well. To begin to achieve this potential, research is needed to define the appropriate match of PV systems to energy end-uses in the commercial building sector. Preliminary findings for a technical assessment of several alternative paths to integrate PV with building energy systems are presented. DOE

MOLTEN CARBONATE FUEL CELL NETWORKS: PRINCIPLES, ANALYSIS, AND PERFORMANCE
J. G. Wimer, M. C. Williams, D. H. Archer (Carnegie-Mellon Univ., Pittsburgh, PA.), and J. F. Osterle (Carnegie-Mellon Univ., Pittsburgh, PA.) 1993 10 p Presented at the 28th Intersociety Energy Conversion Engineering Conference, Atlanta, GA, 8-13 Aug. 1993
(DE93-019872; DOE/METC-C/93/7100; CONF-930804-19) Avail: CASI HC A02/MF A01

Key to the concept of networking is multiple fuel cell stacks with regard to flow of reactant streams. In a fuel cell network, reactant streams are ducted so that they are fed and recycled through stacks in series. Stacks networked in series more closely approach a reversible process, which increases efficiency. Higher total reactant utilizations can be achieved by stacks networked in series. Placing stacks in series also allows reactant streams to be conditioned at different stages of utilization. Between stacks, heat can be consumed or removed, (methane injection, heat exchange)

which improves thermal balance. Composition of streams can be adjusted between stacks by mixing exhaust streams or by injecting reactant streams. Computer simulations demonstrated that a combined cycle system with MCFC stacks networked in series is more efficient than an identical system with MCFC stacks in parallel. DOE

A CALCIUM OXIDE SORBENT PROCESS FOR BULK SEPARATION OF CARBON DIOXIDE
D. P. Harrison, C. Han, and A. Silaban 1993 12 p Presented at the Coal-Fired Power Systems 1993: Advances in IGCC and PFBC Review Meeting, Morgantown, WV, 28-30 Jun. 1993
(Contract DE-AC21-89MC-26366)
(DE93-019288; DOE/MC-26366/93/C0194; CONF-9306148-5) Avail: CASI HC A03/MF A01

Reaction conditions for those runs discussed in this paper are summarized. In tests O2, O3, and O4 the carbonation feed gas consisted of CO2 in N2 in order to establish the ability of the calcined dolomite sorbent to remove CO2 at conditions where the shift reaction could not occur. In the next group of tests (15, 16, 18), the carbonation feed gas contained only CO, H2O, and N2. Any change in feed gas composition would serve as proof that the shift reaction was occurring at the test conditions. CO2 formed by the shift reaction should be removed from the gas phase by reacting with the sorbent. Therefore, this series of tests involved both reactions even though the feed gas contained no CO2. Finally, the feed gas in test 19 contained all of the major components found in a sulfur-free coal-gas. CO2 in the reactor feed as well as that produced by the shift reaction was available for reacting with the sorbent. DOE

FIRST BIOMASS CONFERENCE OF THE AMERICAS: ENERGY, ENVIRONMENT, AGRICULTURE, AND INDUSTRY, VOLUME 2
1993 711 p Conference held in Burlington, VT, 30 Aug. - 2 Sep. 1993
(Contract DE-AC02-83CH-10093)
(DE94-000435; NREL/CP-200-5768-Vol-2; CONF-9308106-Vol-2) Avail: CASI HC A99/MF A06

This conference was designed to provide a national and international forum to support the development of a viable biomass industry. Although papers on research activities and technologies under development that address industry problems comprised part of this conference, an effort was made to focus on scale-up and demonstration projects, technology transfer to end users, and commercial applications of biomass and wastes. The conference was divided into these major subject areas: resource base, power production, transportation fuels, chemicals and products, environmental issues, commercializing biomass projects, biomass energy system studies, and biomass in latin america. The papers in this second volume cover transportation fuels, and chemicals and products. Transportation fuels topics include: biodiesel, pyrolytic liquids, ethanol, methanol and ethers, and commercialization. The chemicals and products section includes specific topics in: research, technology transfer, and commercial systems. Selected papers have been indexed separately for inclusion in the Energy Science and Technology Database. DOE

ADVANCED PROCESSING TECHNOLOGY FOR HIGH-EFFICIENCY THIN-FILM CuInSe2 SOLAR CELLS
D. L. Morel, G. Attar, S. Karthikeyan, A. Muthaiah, and A. Zafar Aug. 1993 32 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-010045; NREL/TP-451-5653) Avail: CASI HC A03/MF A01

This report describes work to develop novel fabrication for CuInSe2 (CIS) solar cells that will result in improved performance and cost effectiveness at the manufacturing level. The primary approach involves all solid-state processing for CIS. This was augmented by work to provide novel alternatives for the formation of the window layer/heterojunction contact. Inherent to the project was the need to develop a generic understanding of the relationship between processing and performance so that broad-based transfer to industry can be facilitated. We achieved good electronic quality CIS by the use of two selenization procedures for predeposited metal layers. We achieved good stoichiometry throughout the bulk of the film, attained grain sizes of up to 1 mu m, and measured electron mobilities of up to 60 cm(exp 2)/V-s. However, there is a complex relationship between grain size, adhesion, and performance. Our primary approach to characterization was to fabricate ZnO/CIS test devices and measure as many properties as possible in device format. We are also developing reactive sputtering of ZnO as an alternative window layer technology. DOE

The US Department of Energy has conducted programs of research and development in hydrogen and related technologies since 1975. The current program is conducted in accordance with the DOE Hydrogen Program Plan FY 1993-FY 1997 which was published in June 1992. The plan establishes program priorities and guidance for the allocation of funding. The core program, currently under the Office of Energy Management, supports projects in the areas of hydrogen production, storage, and systems research. A program review is held annually to evaluate each research project for technical quality, progress, and programmatic benefit. The evaluation is conducted by a panel of technical experts. This proceedings of the program review conducted in May 1993 is a compilation of all research projects supported by the Hydrogen Program during FY 1993. It is produced in the anticipation that it will serve as a useful technical reference for those interested in the status of hydrogen technologies. Selected papers have been indexed separately for inclusion in the Energy Science and Technology Database. DOE

STABLE, HIGH-EFFICIENCY AMORPHOUS-SILICON SOLAR CELLS WITH LOW HYDROGEN CONTENT
S. S. Hegedus (Delaware Univ., Newark.) and J. E. Phillips (Delaware Univ., Newark.) Aug. 1993 60 p
(Contract DE-AC02-83CH-10093)
(DE93-018214; NREL/TP-451-5756) Avail: CASI HC A04/MF A01

This report describes a 21-month project to demonstrate amorphous-silicon (a-Si) solar cells with high stabilized conversion efficiency. The objective was to develop a research program spanning material issues (more stable a-Si and better a-SiGe alloys) and device issues (more stable a-Si-based solar cells) with the goal of high stabilized solar cell efficiency. The Institute of Energy Conversion (IEC) produced and analyzed the stability of a-Si films and solar cells with reduced hydrogen content (2-6%). A thermodynamic model of defect formation was developed that describes the high-temperature degraded state of a solar cell. An analysis of bi-facial current voltage and quantum efficiency results for a-SiGe p-i-n devices with transparent front and back contacts provided information about the influence of alloying and band-gap grading on hole and electron collection. IEC also studied the stability of graded and ungraded a-SiGe solar cells using bifacial devices to learn about the relative degradation of hole and electron collection, and concludes that degradation of the photoconductivity of a-SiGe materials does not agree with degradation observed in solar cells. DOE

CATHODE MATERIALS FOR THE MOLTEN CARBONATE FUEL CELL
G. H. Kucera, A. P. Brown, M. F. Roche, E. J. Indacochea, M. Krumpelt, and K. M. Myles 1993 13 p Presented at the 206th ACS National Meeting, Chicago, IL, 22-27 Aug. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE93-019515; ANL/CMT/CP-79775; CONF-930802-11) Avail: CASI HC A03

Both LiFeO2 and Li2MnO3 were stable in the cathode environment, had low solubility, and were nonprecipitating in the anode environment. Dopants were employed to enhance the electronic conductivity of both materials. Cobalt-doped LiFeO2 was a factor of 30 more conductive than the undoped LiFeO2; Nb-doped Li2MnO3 was a factor of 60 more conductive than its undoped form. However, only the Co-doped LiFeO2 exhibited the desired p-type conduction. Half- and full-cell tests with Co-doped LiFeO2 as the cathode material showed that its performance strongly depended on the oxygen partial pressure. Under simulated high-pressure conditions, where the O2 partial pressure was 70 kPa, the performance was good. LiCoO2 had low solubility and was a good electronic conductor undoped. In addition, it exhibited p-type conduction, and, when used as a cathode material, gave good cell performance. It precipitated as cobalt metal under reducing conditions in anode. However, neither rate of deposition nor conditions influencing deposition and location are known. DOE

THE ELECTROCHEMICAL PERFORMANCE OF THIN-ELECTROLYTE SOLID OXIDE FUEL CELLS
D. Zurawski and T. Kueper 1993 3 p Presented at the 184th Meeting of the Electrochemical Society, New Orleans, LA, 10-15 Oct. 1993
(Contract W-31-109-eng-38)
(DE93-041184; ANL/CMT/CP-79617; CONF-931024-3) Avail: CASI HC A01/MF A01

Several benefits are realized by lowering the operating temperature of solid oxide fuel cells (SOFC's) from 1000C to temperatures in the 600 to 800C range. Among the advantages are decreased reaction between fuel cell components, shorter startup times, and the possibility of using metals in stack construction; however, the achievable power density in conventional SOFC's is too low. A strategy for overcoming this limitation is to decrease the thickness of this layer by approximately an order of magnitude. Thin (5 micron electrolyte SOFC's have recently been fabricated by Allied-Signal Aerospace Systems and Equipment Company (ASASE). The electrochemical performance of these cells has been studied and is discussed. DOE

THE FY1992 SURVEY ON MULTI-PURPOSE DAM AND ENERGY UTILIZATION SYSTEM BY THE WIND POWER GENERATION ERATION
Mar. 1993 204 p In JAPANESE
(DE94-707408; ETDE/JP-mf-94707408) Avail: CASI HC A10/MF A03

The wind power generation for power supply necessary for pumping for water-use works using underground dam which were pushed at Miyako Island, Okinawa is described. The survey aims to study economic effects of introduction of the wind power generation system by setting areas for irrigation. The field area, which is irrigable by three units of USW's 100kW wind power generator as a load follow-up system, is 100ha. Surplus power, when purchased by power companies, is appropriated for maintenance cost for irrigation and makes farmers' running cost nothing. Even though depreciation expenses and interest rates of the initial cost which is construction cost of the wind power generation system are borne, the system possibly pays. Since a public subsidy is expected to be given to the initial cost portion, burdens of farmers become much lighter. By using an inverter pump system, the number of operated pumps and the revolution number of the pump can be controlled so as to make all output of the wind turbine consume as power of the pump. So the system which is minimum in running cost can be obtained. DOE

CURRENT SITUATION OF DEVELOPMENT OF PETROLEUM SUBSTITUTING ENERGIES (USA)
Mar. 1993 52 p In JAPANESE
(DE94-707492; NEDO-P-9201) Avail: CASI HC A04/MF A01

Trends in development of petroleum substituting energies in the U.S.A. are described. Among non-fossil fuel based energies currently available, nuclear power generation (7%), biomass power generation (4%), and hydraulic power generation (3%) account for a large part. The future for the nuclear energy is opaque. Biomasses are anticipated to be the largest

regenerative energy source. Solar energy was regarded to be a future energy source, but its cost effect is not still good. While geothermal power generation produces 0.1% of the entire energy, its future is bright. Ocean energies of all types of form such as sea water thermal energy conversion and wave energy were not treated as a substituting energy in the U.S.A. Multi-fuel vehicles using gasoline, methanol, and ethanol are estimated to account for 25% of vehicle operations in the U.S.A. by 2000. Electric vehicles for practical use would be a hybrid type combining electric motors and gasoline engines. DOE

CURRENT SITUATION OF DEVELOPMENT OF PETROLEUM SUBSTITUTING ENERGIES (CANADA)
Mar. 1993 31 p In JAPANESE
(DE94-707493; NEDO-P-9202) Avail: CASI HC A03/MF A01

Trends in development of petroleum substituting energies in Canada are described. Those fuels being put into practical use as substituting fuels in the transportation sector are natural gas, propane gas, methanol, hydrogen, and electric power. An architectural energy technology improving project was inaugurated on air conditioning, ventilation, and illumination in buildings that consume 34% of the entire energy. The IERD program was implemented by the bureau of efficient substituting energy technologies of CANMET on the research and development in industrial areas. Since having been introduced in 1977, this project has extended assistance to about 80 cases in industrial areas, of which 50% have achieved technical successes and were commercialized. With respect to bio energies, methods for effectively utilizing wastes that are difficult to treat are drawing attention. Research and development are being moved forward to put into practical use the solar energy, wind power, and small-scale regenerative energies. DOE

THE FY1992 SURVEY ON COMMERCIALIZATION OF STIRLING ENGINE UTILIZATION EQUIPMENT
Mar. 1993 103 p In JAPANESE
(DE94-707416; ETDE/JP-mf-94707416) Avail: CASI HC A06/MF A02

Problems on commercialization of Stirling engine heat pumps (SEHP) and the solution are studied. The Stirling engine is a small and fixed engine having a 30-40% thermal efficiency and a 1-100 kW output. It is a closed recipro type external combustion engine with non-condensable gas like helium as working fluid. Its theoretical efficiency agrees with that of the Carnot's cycle. This is because the Stirling engine is often called a dream engine. However, the Stirling engine is legally restricted from a viewpoint of ensuring safety because high pressure gas as working fluid is sealed into the Stirling engine. It is feared that this point will be a condition that restricts spread/promotion of the equipment which uses the engine. Therefore, by guidance of MITI and support of organizations/enterprises concerned, a committee was started in 1992FY and studied the safety of the Stirling engine and the related legal systems. DOE

N94-22030# New Energy and Industrial Technology Development Organization, Tokyo (Japan).
PRESENT STATUS OF DEVELOPING PETROLEUM-SUBSTITUTING ENERGY (EC)
Mar. 1993 58 p In JAPANESE
(DE94-707494; NEDO-P-9204) Avail: CASI HC A04/MF A01

The EC has had approximately 50% of its total energy demand supplied by imports from the exterior of the Community. Hence, it is getting important to develop oil-substituting renewable energy as well as to curtail the emission of carbon dioxide. In consideration of these situations, the results of investigation on the energy policy of the European Community are described. The policy comprises three courses: European Energy Charter, formation of an open European Community energy market, and environmental conservation. Particularly, concerning the reduction of carbon dioxide emission, the EC Council has decided to introduce carbon dioxide taxation so as to suppress the carbon dioxide emission in the year 2000 to the 1990 level. The arrangement for its introduction, however, encountered with difficulties because of the opposition of various countries other than the European Community and the industrial world of the European Community. Legislation of the investment promotion law for energy saving and the construction of infrastructure footing and an information network are ineffective due to the sluggish fuel price and economic recession. A plurality of EC member countries are advancing a comprehensive activity within the framework of the joint programs of research, development, and demonstration set for the renewable energy policy ensuring energy supply and environmental harmonization. DOE

INVESTIGATION ON THE CHEMICALLY FIXING TECHNIQUE OF CARBON DIOXIDE UTILIZING SOLAR ENERGY
Mar. 1993 83 p
(DE94-714886; NEDO-GET-9208) Avail: CASI HC A05/MF A01

This report describes the results of an effective fixing technique of CO2 by utilizing solar energy. First of all, the investigation was directed to the technique for synthesizing ethylene, hydrocarbons, and alcohol by electrochemical reduction of CO2. The power required for this process is supplied by photovoltaic power generation. Development of an excellent electrode catalyst is needed because the reduction of CO2 requires a high overvoltage. It is desirable to enhance the selectivity of the reaction for specific material and improve the transport process in the electrolytic cell. Next, the designing of materials and the reaction of photocatalysts using semiconductor electrode and semiconductor particulate was examined. A semiconductor electrode made of FeS2 is inexpensive and is very efficient at collecting solar light. In the category of a photocatalysis system, a photocatalytic system in which semiconductor particles are embedded in a vesicle and a photocatalyst based on potassium niobate are noteworthy. As biosystem, the method of reducing CO2 by calcareous algae which simultaneously advances fixing and calcification of CO2 by photosynthesis is noteworthy. DOE

STUDY ON POSSIBILITY OF DEVELOPING ENERGY INTEGRATION TECHNOLOGY
Mar. 1993 154 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(DE94-714903; NEDO-P-9220) Avail: Issuing Activity (Department of Energy (DOE))

Developments of conventional individual technologies were re-identified drastically and collectively to study the possibility of developing them as an energy integration technology. In addition, the theory for energy supplier side alone was eliminated, and the user side theory and considerations on

environments and human being were valued more importantly. In its bottom-up approaches, existing technologies are first identified transversely, their existing drawbacks are compensated, and other industrial technologies are introduced freely using the key technology as a nucleus. The present study has taken up diverse utilization of the inexhaustible solar energy and development of new energy storing technologies. In its top-down approaches, a proposition was set beginning with thinking what the ideal type could be for energy systems, and pursuits were made along stratified structures. The user side theory was emphasized to impart organic combined functions within the flows of supply and utilization. Energy conversion, storage, and transportation were assembled into one converged integrated function so that diversified energy supply sources may be dealt with efficiently. Non-thermal utilization of chemical energies remains a problem yet to be solved. DOE

SURVEYS ON SPECIFIC PATTERNS OF FACILITY INTALLATION OF PHOTOVOLTAIC POWER GENERATING TECHNOLOGIES FOR INTERNATIONAL COOPERATION
Mar. 1993 161 p In JAPANESE
(DE94-714901; NEDO-P-9218) Avail: CASI HC A08/MF A02

The objective is to contribute to the international introduction of photovoltaic power generation. To do this, its load patterns, device constitution, land areas, and prices were rearranged and standardized so that design standardization and efficiency improvement may be achieved, and appropriate introduction patterns may be selected from climatic conditions at various sites. Areas dealt with are Africa, Asia, Oceania, and South and Central America. The basic design consists of combination of solar cells with storage batteries for DC load, whereas inverters were added for AC load. Facility capacities were designed so that they can be calculated by assuming general load menus comprising lighting, pumps, and electric appliances, as well as load patterns. Because of non-electrified areas requiring insolation to take care of all of the annual load, minimum monthly average insolation on slopes was used to calculate solar cell capacities. While storage battery capacities will be established upon investigating climatic conditions at proposed sites, arrangements were made on selecting charge controllers that can avoid overcharging and overdischarging due to variation in insolation. A design procedure document was prepared so that the basic design could be carried out efficiently. DOE

RESEARCH ON STABLE, HIGH-EFFICIENCY AMORPHOUS SILICON MULTIJUNCTION MODULES
M. Ghosh, F. Kampas, and J. Xi Sep. 1993 11 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE93-018220; NREL/TP-411-5760) Avail: CASI HC A03/MF A01

This report describes progress made in the first half of Phase 2 of a three-phase program to develop high-efficiency, same-band-gap, amorphous-silicon, tandem-junction modules. Results for both 1-cm(exp 2) devices and 0.3-m (0.09-m(exp 2)) modules are given. Considerable effort was devoted to finding a device structure and layer conditions that reconcile the conflicting requirements of a good 'tunnel junction' contact between the two stacks and a high-efficiency device. High-band-gap p(sub 2) layers, which enable good voltage and current from the second stack, were found to result in poor tunnel junctions. The best results were obtained by using a thin (1-nm-thick) p(sup +) layer (no carbon) between the n(sub 1) and p(sub 2) layers of the device. DOE

HEALTH EFFECTS OF GLOBAL WARMING: PROBLEMS IN ASSESSMENT
J. Longstreth Jun. 1993 11 p Presented at the International Conference on Comparative Risks Analysis of Air Pollution Issues and Priority Setting, Denver, CO, 6-11 Jun. 1993
(Contract DE-AC06-76RL-01830)
(DE93-040323; PNL-SA-22711; CONF-930656-1) Avail: CASI HC A03/MF A01

Global warming is likely to result in a variety of environmental effects ranging from impacts on species diversity, changes in population size in flora and fauna, increases in sea level, and possible impacts on the primary productivity of the sea. Potential impacts on human health and welfare have included possible increases in heat related mortality, changes in the distribution of disease vectors, and possible impacts on respiratory diseases including hayfever and asthma. Most of the focus thus far is on effects which are directly related to increases in temperature, e.g., heat stress or perhaps one step removed, e.g., changes in vector distribution. Some of the more severe impacts are likely to be much less direct, e.g., increases in migration due to agricultural failure following prolonged droughts. This paper discusses two possible approaches to the study of these less-direct impacts of global warming and presents information from on-going research using each of these approaches. DOE

TECHNOLOGY TO PREVENT GREENHOUSE EFFECT GASES Survey Report, FY 1992
Mar. 1993 100 p In JAPANESE
(DE94-707421; ETDE/JP-MF-94707421) Avail: CASI HC A05/MF A02

This paper makes studies on technology for CO2 deepsea storage, hydrate behavior, and CO2 biological effects. Accumulation and evaluation of more technical information/knowledge are required for CO2 transportation to the deepsea bottom in consideration of costs of CO2 separation/transportation and minimizing CO2 environmental effects. It is also required to accumulate thermodynamical property data and kinetic data on CO2/hydrates in the deepsea at temperatures of 1-4 C and at pressures over 30 MPa. Part of CO2 dissolves and diffuses into the ocean, and the rest forms solid particulate CO2/hydrates. The CO2 resultantly forms complicated solid-liquid mixed phase flows, which have serious effects on the mass transfer process. Investigation is made on the model predicting CO2 diffusion in the deepsea bottom. CO2 effects on deepsea organisms and possible ecosystem changes including food chain are also studied. It is difficult for higher organisms to survive in the liquid CO2 reservoir area, and pH becomes a problem in the diffusion area. A simulation model on the whole ecosystem is necessary to be made for elucidation. DOE

MANUAL OF DRANC (RELEASE 1.1): A COMPUTER PROGRAM FOR THE DUTCH RISK ASSESSMENT OF NEW CHEMICAL SUBSTANCES
C. J. M. Visser and C. Toet 1992 29 p See also PB90-248980, PB93-102309, PB93-102317 and PB93-178184. Sponsored by Directorate-General for Environmental Protection, Leidschendam (Netherlands) Sponsored by Directorate-General for Environmental Protection, Leidschendam (Netherlands)
(PB93-194827; RIVM-679102010) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In the project, 'Evaluation System of New Substances', methods are developed to systematically predict and assess the hazards for man and environment related to the production and use of new chemical substances. Part of the project is the realization of a risk assessment system for new chemicals. Currently this system has the form of the computer program DRANC (Dutch Risk Assessment system for New Chemicals). The program is available for advisory tasks concerning the assessment of hazard and risk of new chemical substances (level 0, 1-100 ton/year). The manual describes the use of the program DRANC (version 1.1), which was developed using Turbo Pascal and can be run on all MS-DOS computers. NTIS

PARAMETERS AFFECTING HYDROGEN CHLORIDE MEASUREMENTS Final Report
L. R. Martin, N. A. Abul-Haj, Douglas M. Brenner, and Karl R. Westberg Jun. 1993 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-85-C-0086)
(AD-A271326; AFESC/ESL-TR-89-23) Avail: CASI HC A03

The launching of solid rocket boosters releases numerous gases including hydrogen chloride. Monitoring the concentrations of these gases and predicting their atmospheric transport is required for safety reasons and for compliance with environmental laws. Monitoring of these gases is difficult because they are hydrophilic and tend to condense on atmospheric aerosols. Once such gases are condensed on the atmospheric aerosols, they will not appear on gas-phase sensors unless provision is made to evaporate the aerosols. Transport of the gases will also be governed by the chemistry in the aerosols and movement of the aerosols in the atmosphere, as opposed to the gas-phase chemistry alone. The objective of this project is to investigate the behavior of hydrogen chloride in the presence of atmospheric aerosols. The thermodynamics of HCl in the gas and liquid phase will be reviewed, and kinetics of mass transfer, diffusivity, and sticking coefficients on water of HCl will be measured. The evaporation of atmospheric aerosols will also be discussed. DTIC

TECHNOLOGY TO PREVENT GREENHOUSE EFFECT GASES Survey Report, FY 1992
Mar. 1993 193 p In JAPANESE
(DE94-707420; ETDE/JP-MF-94707420) Avail: CASI HC A09/MF A03

A direction to an environmental harmony type industrial technology system is proposed by grasping the total CO2 emission by linking the interindustry relations analysis and CO2 emissions from each industrial sector. Scenarios are made for fields of electricity, iron/steel, transportation, and residential/commercial use. In transportation and residential/commercial sectors where there is still room for energy conservation, energy conservation is set as a main theme of the scenario. In energy conversion, main themes of the scenario are energy conversion in demand fields which considers electrification increasingly adopted in lifestyle and the corresponding increase in a percentage of the nuclear power generation in a total power generation amount. As for industrial location, a scenario is made with dispersed location in the iron/steel industry as a model. Concerning CO2 reduction effects, CO2 can be reduced 9.8% if all the power plants to be newly installed are made nuclear power plants, 7.9% if all the fossil fuels consumed in automobile transportation and residential/commercial sectors are converted to electricity, 3.4% if energy conservation of 10% can be achieved in transportation and residential/commercial sectors, and 11.2% if iron-making processes in the iron/steel industry are dispersedly located. When CO2 emission in 2010 is maintained at the 1990 level, the economic growth rate will be 1.6%. To attain an economic growth rate of 2.5%, it is necessary to carry out the above-mentioned drastic policies. DOE

INTRUSION OF STRATOSPHERIC OZONE IN THE TROPOSPHERE THROUGH TROPOPAUSE FOLDING AND COLD AIR DROPLETS [INTRUSION STRATOSPHAERISCHEN OZONS IN DIE TROPOSPHAERE DURCH TROPOPAUSENFALTUNGEN UND KALTLUFTTROPFEN]
Andreas Oberreuter 1992 173 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Rept-87; ETN-93-95065) Avail: CASI HC A08

The mutual exchange of ozone rich air from the stratosphere with ozone lean air from the troposhere is simulated using the EURAD (European Acid Deposition) model. Ozone concentrations in 22 model layers between Earth ground and 100 hPa were estimated. Vertical fluxes in several model heights, horizontal fluxes at lateral limits of model area, and dry deposition of ozone at Earth ground were investigated. The influence of a cold air droplet on the vertical flow of stratospheric ozone was separately examined. Clouds influence on ozone transport was also studied. A drop of ozone concentration above the tropopause and an increase under this one are found. It is noticed that dynamic processes are responsible for an enhancement of ozone flow through clouds appearing in the middle troposphere. ESA

ROLE OF SURFACE CHARACTERISTICS IN URBAN METEOROLOGY AND AIR QUALITY Ph.D. Thesis
D. J. Sailor Aug. 1993 174 p
(Contract DE-AC03-76SF-00098)
(DE93-040929; LBL-34459) Avail: CASI HC A08/MF A02

Urbanization results in a landscape with significantly modified surface characteristics. The lower values of reflectivity to solar radiation, surface moisture availability, and vegetative cover, along with the higher values of anthropogenic heat release and surface roughness combine to result higher

air temperatures in urban areas relative to their rural counterparts. Through their role in the surface energy balance and surface exchange processes, these surface characteristics are capable of modifying the local meteorology. The impacts on wind speeds, air temperatures, and mixing heights are of particular importance, as they have significant implications in terms of urban energy use and air quality. This research presents several major improvements to the meteorological modeling methodology for highly heterogeneous terrain. A land-use data-base is implemented to provide accurate specification of surface characteristic variability in simulations of the Los Angeles Basin. Several vegetation parameterizations are developed and implemented, and a method for including anthropogenic heat release into the model physics is presented. These modeling advancements are then used in a series of three-dimensional simulations which were developed to investigate the potential meteorological impact of several mitigation strategies. Results indicate that application of moderate tree-planting and urban-lightening programs in Los Angeles may produce summertime air temperature reductions on the order of 4 C with a concomitant reduction in air pollution. The analysis also reveals several mechanisms whereby the application of these mitigation strategies may potentially increase pollutant concentrations. The pollution and energy use consequences are discussed in detail. DOE

(DE94-000748; DOE/ER-61493/1) Avail: CASI HC A03/MF A01

In recognition of the role of plants in the bio-geosphere carbon cycle, the Department of Energy (OHER) initiated a research program: The Direct Effects of Increasing Carbon Dioxide on Vegetation. This report describes the continuing research that we are conducting as part of this program. The ultimate goal of our research is to develop computer models capable of predicting responses of plants and ecosystems to the direct and indirect effects of atmospheric levels of carbon dioxide that are approximately twice those of the pre-industrial period. The understanding of ecosystem responses to elevated CO2 necessarily depends on knowledge of responses of individual plants and their interactions with one another and their environment. Our research approach incorporates the study and modeling of response to CO2 at all levels of the plant-community-ecosystem hierarchy, in an effort to understand the linkages and translation of effects of CO2 from one level to another. The research results reported here focus at several different levels of this hierarchy, and are highlights of accomplishments for the period September 1992 to June 1993. DOE

GLOBAL EMISSIONS AND MODELS OF PHOTOCHEMICALLY ACTIVE COMPOUNDS
J. E. Penner, C. S. Atherton, and T. E. Graedel (Bell Telephone Labs., Inc., Murray Hill, NJ.) 20 May 1993 28 p Presented at the 1st International Global Atmospheric Chemistry Project Conference, Elat, Israel, 18-22 Apr. 1993
(Contract W-7405-eng-48)
(DE93-040490; UCRL-JC-112273; CONF-930443-1) Avail: CASI HC A03/MF A01

Anthropogenic emissions from industrial activity, fossil fuel combustion, and biomass burning are now known to be large enough (relative to natural sources) to perturb the chemistry of vast regions of the troposphere. A goal of the IGAC Global Emissions Inventory Activity (GEIA) is to provide authoritative and reliable emissions inventories on a 1 deg x 1 deg grid. When combined with atmospheric photochemical models, these high quality emissions inventories may be used to predict the concentrations of major photochemical products. Comparison of model results with measurements of pertinent species allows us to understand whether there are major shortcomings in our understanding of tropospheric photochemistry, the budgets and transport of trace species, and their effects in the atmosphere. Through this activity, we are building the capability to make confident predictions of the future consequences of anthropogenic emissions. This paper compares IGAC recommended emissions inventories for reactive nitrogen and sulfur dioxide to those that have been in use previously. We also present results from the three-dimensional LLNL atmospheric chemistry model that show how emissions of anthropogenic nitrogen oxides might potentially affect tropospheric ozone and OH concentrations and how emissions of anthropogenic sulfur increase sulfate aerosol loadings. ATMOSPHERIC SAMPLING GLOW DISCHARGE IONIZATION AND TRIPLE QUADRUPOLE TANDEM MASS SPECTROMETRY FOR EXPLOSIVES VAPOR DETECTION
S. A. McLuckey, D. E. Goeringer, K. G. Asano, K. J. Hart, G. L. Glish, B. C. Grant, and D. M. Chambers Aug. 1993 166 p
(Contract DE-AC05-84OR-21400)
(DE93-040593; ORNL/TM-12434) Avail: CASI HC A08/MF A02

The detection and identification of trace vapors of hidden high explosives is an excellent example of a targeted analysis problem. It is desirable to push to ever lower levels the quantity or concentration of explosives material that provides an analytical signal, while at the same time discriminating against all other uninteresting material. The detection system must therefore combine high sensitivity with high specificity. This report describes the philosophy behind the use of atmospheric sampling glow discharge ionization, which is a sensitive, rugged, and convenient means for forming anions from explosives molecules, with tandem mass spectrometry, which provides unparalleled specificity in the identification of explosives-related ions. Forms of tandem mass spectrometry are compared and contrasted to provide a summary of the characteristics to be expected from an explosives detector employing mass spectrometry/mass spectrometry. The instrument developed for the FAA, an atmospheric sampling glow discharge/triple quadrupole mass spectrometer, is described in detail with particular emphasis on the ion source/spectrometer interface and on the capabilities of the spectrometer. Performance characteristics of the system are also described as they pertain to explosives of interest including a description of an automated procedure for the detection and identification of specific explosives. A comparison of various tandem mass spectrometers mated with atmospheric sampling glow discharge is then described and preliminary studies with a vapor preconcentration system provided by the FAA are described. THE USE OF LIDAR FOR THE EVALUATION OF TRAFFIC-RELATED URBAN POLLUTION
W. Eichinger, D. Cooper, W. Buttler, W. Cottingame, and L. Tellier 1993 11 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-000704; LA-UR-93-3437; CONF-930722-46) Avail: CASI HC A03

Lidar (Light Detection and Ranging) is demonstrated as a tool for the detection and tracking of sources of aerosol pollution. Existing elastic lidars have been used to demonstrate the potential of the application of this technology in urban areas. Data from several experiments is shown along with analysis methods used for interpretation of the data. The goal of the project is to develop a light-weight, low-cost, lidar system and data analysis methods which can be used by urban planners and local air quality managers. The ability to determine the sources, i.e. causes, of non-attainment may lead to more effective use of tax dollars. Future directions for the project are also discussed. DOE

SURVEY ON CHEMICAL ENGINEERING TECHNOLOGIES FOR THE GLOBAL ENVIRONMENTAL PROTECTION
Mar. 1993 165 p In JAPANESE
(DE94-714887; NEDO-GET-9209) Avail: CASI HC A08/MF A02

The present paper suggests measures to suppress and reduce global greenhouse gases. Under the control of artificial environments such as bioreactors, hydroponics, and vegetable factories, a very high fixing rate of CO2 can be obtained, but CO2 generation as a byproduct of electric power consumption is also large. It is preferable to use methane as a resource by reforming reactions or selective oxidative reaction. In the recovery of fluorocarbons, 100% recovery is desirable. Techniques for decomposing recovered fluorocarbon and converting it to harmless material are the most immature ones. An understanding of the essential structural

relationship of coal is necessary for establishing combustion techniques for the reduction of N2O. An integrated power generation system composed of a solid electrolyte fuel cell, a coal gasification process, and a superheat pump system form the basis for a technology that imposes no burden on the global environment. Establishment of purification techniques for industrial- or living-related drainage to a closed water area system are discussed.

SURVEY ON EVALUATION OF ENERGY TECHNOLOGY CONTRIBUTING TO PRESERVATION OF THE GLOBAL ENVIRONMENT. 2
Mar. 1993 289 p In JAPANESE
(DE94-714884; NEDO-GET-9205) Avail: CASI HC A13/MF A03

The analysis and evaluation are made on effectiveness of each of the energy technologies having large effects on control of greenhouse effect gas emissions. Details of the report based on the Framework Convention on Climate Change of the United Nations Conference on Environment and Development should essentially be made by efforts spontaneously exerted by countries now being in economic transition and development. The required database, however, has not necessarily been prepared. It is, therefore, necessary that developed countries should assist the countries in preparing methodology for estimating emission and absorption of greenhouse effect gases and methodology or know-how for working out domestic or regional plans. As for 'IPCC/EIS-IIASA International Workshop', discussions on the following are reported: energy-related greenhouse gases reduction and removal, analysis of factors affecting energy consumption and CO2 emissions and their regional and sectoral differences, and assessment of technologies for reducing CO2 emission. Also introduced is a report of the Eighth Session on the Inter-governmental Panel on Climate Change. DOE

INVESTIGATION ON CONSTRUCTION OF THE DATABASE SYSTEM FOR RESEARCH AND DEVELOPMENT OF THE GLOBAL ENVIRONMENT INDUSTRY TECHNOLOGY
Mar. 1993 177 p In JAPANESE
(DE94-714890; NEDO-GET-9210-5) Avail: CASI HC A09/MF A02

This paper studies a concrete plan to introduce a new database system for the Research Institute of Innovative Technology for the Earth (RITE). RITE is necessary to promote the development of industrial technology that will bring about solutions to the global environmental problem. Specifications for the system introduction are concerned with maker selection, operating system, detailed schedule for introduction, etc. The RITE inhouse database has problems with its operating system and its maintenance cost, and it is apt to have a large construction cost in comparison with its utilization factor. Further study is made on its introduction. Information provided by the inhouse database is only the one owned by the organization, and information outside the organization is provided by the external database. The information is registered and selected by the registerer. The access network is set by personal computer network at the beginning and is set to transit to INTERNET in the future. For practical construction of the system, it is necessary to make the user's needs clear for the system design and to adjust functions between hardware systems.

INVESTIGATIONS ON TRENDS IN GLOBAL ENVIRONMENT ADAPTIVE INDUSTRIAL TECHNOLOGIES
Mar. 1993 121 p In JAPANESE
(DE94-714888; NEDO-GET-9210-1) Avail: CASI HC A06/MF A02

This paper describes specific evaluations on measures to reduce carbon dioxide chemically, and measures to reduce non-carbon dioxide greenhouse gases. The former measures could reduce CO2 by 10% to 20% by improving energy utilization and using unutilized energy recovering technologies. The key to fixing CO2 through hydrogenation is how to ensure the hydrogen availability. During the coming two decades, the Japanese chemical industry is expected to reduce CO2 of about ten million tons, or about 10%. Use of CO2 oxidizing dehydrogenation process would be capable of reducing CO2 of about five million tons in Japan. For the latter measures, chemical technologies are available to recover and store methane as the greenhouse gas other than CO2. Promotion is urged in combustion technologies to suppress N2O generation, and technologies to treat waste gases from automotive tertiary catalysts and adipic acid processes. Fluorocarbon reduction requires development of technologies to synthesize, recover and treat new substitute materials. Positive measures are also called for to reduce CO, non-methane based hydrocarbons, and NO(x). DOE

SURVEY ON UTILIZATION OF DATABASE FOR RESEARCH AND DEVELOPMENT OF GLOBAL ENVIRONMENTAL INDUSTRY TECHNOLOGY
Mar. 1993 99 p In JAPANESE
(DE94-714891; NEDO-GET-9213) Avail: CASI HC A05/MF A02

To optimize networks and database systems for promotion of the industry technology development contributing to the solution of the global environmental problem, studies are made on reusable information resource and its utilization methods. As reusable information resource, there are external database and network system for researchers' information exchange and for computer use. The external database includes commercial database and academic database. As commercial database, 6 agents and 13 service systems are selected. As academic database, there are NACSIS-IR and the database which is connected with INTERNET in the U.S. These are used in connection with the UNIX academic research network called INTERNET. For connection with INTERNET, a commercial UNIX network service called IIJ which starts service in April 1993 can be used. However, personal computer communication network is used for the time being.

DEVELOPMENT OF ADVANCED CLOUD PARAMETERIZATIONS TO EXAMINE AIR QUALITY, CLOUD PROPERTIES, AND CLOUD-RADIATION FEEDBACK IN MESOSCALE MODELS
In-Young Lee 1993 7 p Presented at the 5th International Energy Conference, Seoul, Republic of Korea, 18-22 Oct. 1993
(Contract W-31-109-eng-38)
(DE93-041164; ANL/ER/CP-80454; CONF-9310173-2) Avail: CASI HC A02/MF A01

The distribution of atmospheric pollutants is governed by dynamic processes that create the general conditions for transport and mixing, by microphysical processes that control the evolution of aerosol and cloud particles, and by chemical processes that transform chemical species and form aerosols. Pollutants emitted into the air can undergo homogeneous gas reactions to create a suitable environment for the production by heterogeneous nucleation of embryos composed of a few molecules. The physicochemical properties of preexisting aerosols interact with newly produced embryos to evolve by heteromolecular diffusion and coagulation. Hygroscopic particles will serve as effective cloud condensation nuclei (CCN), while hydrophobic particles will serve as effective ice-forming nuclei. Clouds form initially by condensation of water vapor on CCN and evolve in a vapor-liquid-solid system by deposition, sublimation, freezing, melting, coagulation, and breakup. Gases and aerosols that enter the clouds undergo aqueous chemical processes and may acidity hydrometer particles. Calculations for solar and longwave radiation fluxes depend on how the respective spectra are modified by absorbers such as H2O, CO2, O3, CH4, N2O, chlorofluorocarbons, and aerosols. However, the flux calculations are more complicated for cloudy skies, because the cloud optical properties are not well defined. In this paper, key processes such as tropospheric chemistry, cloud microphysics parameterizations, and radiation schemes are reviewed in terms of physicochemical processes occurring, and recommendations are made for the development of advanced modules applicable to mesoscale models. ENVIRONMENTAL PROTECTION USING SOCIAL COSTING
R. Lee 1993 4 p Presented at the 1993 Chinese American Academic and Professional Convention, Chicago, IL, 2-5 Jul. 1993
(Contract DE-AC05-84OR-21400)
(DE94-000492; CONF-930796-5) Avail: CASI HC A01/MF A01

Emissions and other residual wastes come from industrial production, commercial and household activities, and transportation. These wastes damage the environment, including human health. As economies grow, so

does concern about balancing that growth with the desire for environmental protection. At issue is how much environmental protection we should have. We address this issue using the concept of social costing. The issue is discussed in the context of electric power generation. There is particular concern about the use of fossil fuels such as petroleum, the major fuel used in the Republic of China, and coal which is the most common fuel used in the U.S. Electric power generation is a major source of airborne pollutants such as SO2, NO(x) particulate matter, volatile organic compounds, CO, and CO2. It also results in liquid and solid wastes, and other effects such as changes in land use. To generate electric power, fuel (such as petroleum, coal or enriched uranium) or some other resource (e.g., wind or geothermal) is needed. A fuel cycle consists of a sequence of activities and processes involved in generating electric power. These activities include the following: fuel extraction, treatment, and processing; fuel conversion into electricity; transmission; waste disposal; and transportation of fuel and wastes between the different stages of the fuel cycle. Each stage results in emissions or other residuals. Several recent studies have been about the environmental costs of electricity. DOE

A KIRCHHOFF APPROACH TO SEISMIC MODELING AND PRESTACK DEPTH MIGRATION
Zhen-Yue Liu May 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1267)
(AD-A271010) Avail: CASI HC A03

The Kirchhoff integral provides a robust method for implementing seismic modeling and prestack depth migration, which can handle lateral velocity variation and turning waves. With a little extra computation cost, the Kirchoff-type migration can obtain multiple outputs that have the same phase but different amplitudes, compared with that of other migration methods. The ratio of these amplitudes is helpful in computing some quantities such as reflection angle. I develop a seismic modeling and prestack depth migration method based on the Kirchhoff integral, that handles both laterally variant velocity and a dip beyond 90 degrees. The method uses a finite-difference algorithm to calculate travel times and WKBJ amplitudes for the Kirchhoff integral. Compared to ray-tracing algorithms, the finite-difference algorithm gives an efficient implementation and single-valued quantities (first arrivals) on output. In my finite difference algorithm, the upwind scheme is used to calculate travel times, and the Crank-Nicolson scheme is used to calculate amplitudes. Moreover, interpolation is applied to save computation cost. The modeling and migration algorithms require a smooth velocity function. I develop a velocity-smoothing technique based on damped least-squares to aid in obtaining a successful migration. DTIC

In this report we summarize the research carried out under this contract on the chaos dynamics analysis of the free sheared atmosphere. Our approach is to expand the fluid equations into finite energy modes rather than in the conventional Fourier analysis. We prove rigorously that our expansion method has the required convergence properties to ensure a satisfactory physical interpretation of the results. For the Taylor-Dyson atmosphere, our analysis, like the Fourier analysis, yields no unstable modes. DTIC

We develop a local scaling theory for structure-function parameters of refractive index and velocity fluctuations in the stably stratified atmospheric boundary layer. The theory relates them to the local values of vertical temperature flux and shearing stress. The theory agrees well with data from observations and from large-eddy simulations. The effects of flow unsteadiness, baroclinity, terrain slope, and breaking gravity waves are apt to cause vertical profiles of temperature flux and shear stress to vary strongly from case to case, making the profiles quite variable as well, but according to the theory the stress and heat flux profiles can generally be diagnosed from those of the structure parameters. The possibility of obtaining ionospheric profile data via tomographic techniques has elicited considerable interest in recent years. The input data for the method is a set of total electron content measurements along intersecting lines of sight which form a grid. This can conveniently be provided by a fast-moving satellite with a VHF beacon which will generate the multiple paths needed for effective tomography. Los Alamos and Sandia National Laboratories will launch and operate the FORTE satellite for the U.S. Department of Energy, with launch scheduled in 1995. FORTE will provide such a beacon. Additionally, wideband VHF receivers aboard the satellite will allow corraborative measurements of ionospheric profile parameters in some cases. DOE

PROCEEDINGS OF THE 15TH ANNUAL SEISMIC RESEARCH SYMPOSIUM Final Report
James F. Lewkowicz and Jeanne M. McPhetres 3 Aug. 1993 444 p Symposium held in Vail, CO, 8-10 Sep. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2309)
(AD-A271458; AD-E201629; PL-TR-93-2160; ERP-1125) Avail: CASI HC A19

This Symposium represents the combined annual review for the seismic verification research programs. The scientific objectives of the research programs are to improve the Air Force's capability to seismically detect, locate, identify, and estimate the yield of underground nuclear explosions. The purpose of these Symposia is to provide the sponsoring agencies an opportunity to review research, particularly contractor research, accomplished during the preceding year and to outline areas of investigation for the coming year. For the researchers, it provides a forum for the exchange of scientific information to help achieve program goals, and an opportunity to meet PL, AFOSR, and NMRO staff to discuss results and future plans. The papers include studies of the identification and characterization of seismic explosion sources (discrimination), intelligent processing of regional seismic signals, the acquisition and processing of seismic data including data from the Commonwealth of Independent States, regional seismic wave propagation from both an empirical and theoretical viewpoint, yield estimation, and laboratory studies of rock properties appropriate to test sites. REMOTE SOUNDING OF TROPOSPHERIC MINOR CONSTITUENTS Final Technical Report, Nov. 1990 - Oct. 1992
S. Roland Drayson, Paul B. Hays, and Jinxue Wang 3 Dec. 1993 49 p
(Grant NAG8-858)
(NASA-CR-194265; NAS 1.26:194265) Avail: CASI HC A03/MF A01

The etalon interferometer, or Fabry-Perot interferometer (FPI), with its high throughput and high spectral resolution was widely used in the remote-sensing measurements of the earth's atmospheric composition, winds, and temperatures. The most recent satellite instruments include the Fabry-Perot interferometer flown on the Dynamics Explorer-2 (DE-2) and the High Resolution Doppler Imager (HRDI) to be flown on the Upper Atmosphere Research Satellite (UARS). These instruments measure the Doppler line profiles of the emission and absorption of certain atmospheric species (such as atomic oxygen) in the visible spectral region. The successful space flight of DE-FPI and the test and delivery of UARS-HRDI demonstrated the extremely high spectral resolution and ruggedness of the etalon system for the remote sensing of earth and planetary atmospheres. Recently, an innovative FPI focal plane detection technique called the Circle-to-Line Interferometer Optical (CLIO) system was invented at the Space Physics Research Laboratory (SPRL). The CLIO simplifies the FPI focal plane detection process by converting the circular rings or fringes into a linear pattern similar to that produced by a conventional spectrometer, while retaining the throughput advantage of the etalon interferometer. CLIO makes the use of linear array detectors more practical and efficient with FPI, the combination of FPI and CLIO represents a very promising new technique for the remote sensing of the lower atmospheres of Earth, Mars, Venus, Neptune, and other planets. The Multiorder Etalon Spectrometer (MOES), as a combination of the rugged etalon and the CLIO, compares very favorably to other spaceborne optical instruments in terms of performance versus complexity. The feasibility of an advanced etalon spectrometer for the remote sensing of tropospheric trace species, particularly carbon monoxide (CO), nitrous oxide (N2O), and methane (CH4) was discussed. The etalon atmospheric spectroscopy techniques are described, instrument design and related technical issues are discussed. The primary objective is to establish the concept of atmospheric spectroscopy with the CLIO and etalon system and its applications for the measurements of tropospheric trace species analyze system requirements and performance, determine the feasibility of components and subsystem implementation with available technology, and develop inversion algorithm for retrieval simulation and data analysis. The effects of several wave types on wind and temperature field in mesosphere and lower thermosphere are studied using a global, fully nonlinear three dimensional circulation model of the middle atmosphere (0 to 150 km). Following results are presented: free mode propagation depends more strongly on mean flow with decreasing wave frequency while momentum deposition of normal modes in the mean flow modifies wind and temperature fields; normal modes, through propagation from Winter hemisphere to Summer hemisphere, cause a dynamic coupling of both hemispheres; thermal tides produce a strong easterly wind in the equatorial lower thermosphere by momentum transfer to the zonal mean flow, caused by dissipation of the diurnal tide near the equator; and thermal tides are generally damped by the nonlinear interaction of tides with normal modes which leads to an excitation of secondary waves and is modified if breaking gravity waves are taken into account. Recent work has shown that natural hydrocarbon emissions can significantly affect the levels of urban and regional tropospheric ozone. We report on the reactivities of these biogenic trace gases, particularly, isoprene, focusing on their importance in the production of aldehydes and peroxy radicals, leading to increased levels of hydrogen over regional forests. Hydrogen peroxide can lead to the wet oxidation of sulfur dioxide to acidic sulfate in aerosols, fogs, and clouds. In turn, acidic sulfate can act as a light scattering aerosol and a source of cloud condensation nuclei (CCN), potentially leading to global cooling. Aerosol sulfate and other dissolved organic and inorganic compounds can also play important roles as a greenhouse species in the lower troposphere. DOE

THE CSIRO 9-LEVEL ATMOSPHERIC GENERAL CIRCULATION MODEL

J. L. McGregor, H. B. Gordon, I. G. Watterson, M. R. Dix, and L. D. Rotstayn 1993 93 p
(CSIRO-TP-26; ISBN-0-643-05250-X) Copyright Avail: Issuing Activity

Numerical models of the general circulation of the atmosphere are an important tool in climate research. They have been used to investigate the dynamical and physical processes controlling the atmosphere. The incorporation of representations of the cryosphere and oceans into such a model allows it to be used for forecasting climate anomalies and climate change. The spectral 9-level Atmospheric General Circulation Model (AGCM) described was developed at the CSIRO Division of Atmospheric Research to provide the basis for the current greenhouse research project and for future research. The spectral method for modeling the general circulation of the atmosphere is now firmly established and was adopted at several major research centers including the National Center for Atmospheric Research (NCAR), the European Centre for Medium-range Weather Forecasting (ECMWF), and the Canadian Climate Center. It provides a cost effective means of atmospheric modeling which is essential for climate research. The version of the CSIRO9 model described was used to generate the implied ocean heat transports required to enable computation of sea temperatures by a slab ocean model rather than using prescribed temperatures. The inclusion of this simple 'mixed-layer' ocean into the model allows the lower boundary condition involving the land surfaces, the polar ice caps, and now the oceans to be self-determining. This form of the CSIRO9 model is currently being used for greenhouse research and will be documented elsewhere. This publication documents the formulation of CSIRO9 and is intended as a general guide to its contents and formulation. It does not give details of the model's computer coding as would be required by users wishing to modify the model. The description of the dynamical framework of the model was kept to a minimum since standard spectral techniques were used. On the other hand, the physical processes are comprehensively covered. For a system that remains in thermodynamic equilibrium, stable equilibria are determined by minimizing an appropriate potential energy function such as the Gibb's free energy. However, when a system does not remain in thermodynamic equilibrium, one cannot use a potential function to derive a state of stable equilibrium. If we assume this is the case for the earth's magnetotail, then we must come up with another method to determine stable equilibrium. We conjecture that this will be a minimum total energy. By combining Poynting's theorem with the Lorentz force equation and Maxwell's equations, one can account for the energy advections into and out of a system containing a fully ionized plasma, as well as for the energy fluctuations caused by changing electric and magnetic fields. By minimizing the total energy equation representing an idealized model of the earth's magnetotail, one should be able to calculate its stable equilibrium state. Although the idealized minimum energy model presented in this paper depicts many trends observed in the earth's magnetotail, this thesis concludes that more modifications are needed before it becomes a useful tool for analyzing the earth's magnetotail. MODELING OF THE COUPLED MAGNETOSPHERIC AND NEUTRAL WIND DYNAMOS Semiannual Technical Status Report No. 1, 1 Apr. - 31 Oct. 1993
Jeff P. Thayer 15 Dec. 1993 10 p
(Grant NAGw-3508; SRI Proj. 4604)
(NASA-CR-194728; NAS 1.26:194728) Avail: CASI HC A02/MF A01

The solar wind interaction with the earth's magnetosphere generates electric fields and currents that flow from the magnetosphere to the ionosphere at high latitudes. Consequently, the neutral atmosphere is subject to the dissipation and conversion of this electrical energy to thermal and mechanical energy through Joule heating and Lorentz forcing. As a result of the mechanical energy stored within the neutral wind (caused in part by Lorentz--and pressure gradient--forces set up by the magnetospheric flux of electrical energy), electric currents and fields can be generated in the ionosphere through the neutral wind dynamo mechanism. At high latitudes this source of electrical energy has been largely ignored in past studies, owing to the assumed dominance of the solar wind/magnetospheric dynamo as an electrical energy source to the ionosphere. However, other researchers have demonstrated that the available electrical energy provided by the neutral wind is significant at high latitudes, particularly in the midnight sector of the polar cap and in the region of the magnetospheric convection reversal. As a result, the conclusions of a number of broad ranging high-latitude investigations may be modified if the neutral-wind contribution to high-latitude electrodynamics is properly accounted for. These include the following: studies assessing solar wind-magnetospheric coupling by comparing the cross polar cap potential with solar wind parameters; research based on the alignment of particle precipitation with convection or field aligned current boundaries; and synoptic investigations attributing seasonal variations in the observed electric field and current patterns to external sources. These research topics have been initiated by satellite and ground-based observations and have been attributed to magnetospheric causes. However, the contribution of the neutral wind to the high-latitude electric field and current systems and their seasonal and local time dependence has yet to be quantitatively evaluated. In this program, we are evaluating the coupled magnetospheric and neutral wind dynamos at high latitudes under various conditions. In addition to examining the impact of seasonal variations, we are investigating the consequences of the separate dynamos having pure current-source or voltage-source behaviors.

MOBILITY OF SALT DOMES [MOBILITEIT VAN ZOUTKOEPELS]
J. H. A. Bosch (Rijks Geologische Dienst, Haarlem, Netherlands.) Aug. 1992 12 p In DUTCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(BCRS-92-08; ISBN-9-05-411046-5; ETN-93-93316) Avail: CASI HC A03

The mobility of salt domes in the northeast Netherlands was studied using LANDSAT Thematic Mapper and SPOT satellite pictures with a view to the underground storage of chemical and radioactive wastes. The detection of salt diapirism is important because it affects the water budget around a salt dome and hence the stability of the dome. However, the satellite picture did not allow determination of recent tectonic motion of the salt domes. In areas not overgrown with vegetation, several types of soil were identified which illustrate the recent geological history of these areas. ESA

In the remote measurement of tropospheric temperature with a rotational Raman lidar a perturbation of the Raman signal by elastic backscattering from molecules and aerosols occurs. This background is hard to suppress with conventional means such as gratings and filters because of the small spectral separation from the rotational Raman signal. An atomic vapor filter is a promising candidate for suppressing this background. It is obvious that this scheme can only be used if the lidar output wavelength coincides with the wavelength of a suitable atomic transition. The development and testing of narrow band filters made of atomic thallium vapor with and without the addition of argon is described. An application of a thallium atomic vapor filter may be the GKSS lidar project ATLAS (Advanced Temperature and humidity Lidar for Atmospheric Studies) with an output wavelength of 276.787 nanometer. A procedure for the preparation of thallium absorption cells made of fused silica is presented. Transmission spectra of two thallium filters, measured with a frequency doubled dye laser, show that the filter properties required for ATLAS are met by a thallium atomic vapor filter without argon. The addition of argon results in an undesired attenuation of the rotational Raman signal at high thallium temperatures. ESA

(BONN-IR-92-45; ETN-93-93811) Avail: CASI HC A04

Six rocket borne ionization gages launched during the METAL campaign were employed to deduce profiles of turbulent energy dissipation rate (epsilon) in the polar mesosphere in Sep. and Oct. 1991. Very small activity of turbulence was found. The influence of epsilon on the energy budget of the polar mesosphere in Autumn is shown to be small in comparison to other heating and cooling effects. After METAL, a new gage for simultaneous measurements of electron and neutral densities was developed in order to improve the overall time constant of the instrument. The operational parameters of this instrument were optimized in the laboratory using vacuum facilities of the plasma chamber. The instrument allows spatial high resolution measurements of temperature and density with a strongly reduced time constant and its stability was proved by vibration tests in view of an implementation on a research rocket. THE EFFECTS OF MAGNETIC STORM PHASES ON F-LAYER IRREGULARITIES FROM AURORAL TO EQUATORIAL LATITUDES Quarterly Report, 1 Jul. - 30 Sep. 1993
Jules Aarons and Michael Mendillo 30 Sep. 1993 4 p
(Contract N00014-89-J-1754)
(AD-A272685) Avail: CASI HC A01/MF A01

Although the general pattern of equatorial F-layer irregularities as a function of latitude, longitude, and geophysical conditions is in hand, the day to day variations are still difficult to evaluate. The forcing functions for day to day variations appear to be neutral winds and electric field conditions. The data indicate that at times in 'the irregularity season', irregularities are produced day after day. However nights of irregularities are at other times followed by one or more nights with an absence of irregularities. For the equatorial region, using scintillation data at 136 MHz, we have correlated the occurrence of irregularities at several stations along a relatively narrow range of longitudes at various latitudes in the Pacific sector. The sites used are in the Philippines, Taiwan, and Korea. The correlation of daily occurrence was poor. For example at magnetically quiet times there are irregularities noted at a station such as Osan, Korea (dip latitude 30 deg) with little irregularity activity at Manila (dip latitude 5 deg), relatively close in longitude. For latitudes somewhat higher than the anomaly region, the problem arises of separating polewards effects of the equatorial plumes and the equatorwards motion of irregularity development originating in the auroral region during severe magnetic storms. A possibility exists for the generation of another class of F-layer irregularities at mid-latitudes with a body of data from Japan, Port Moresby, Osan, and Palehua, Hawaii. This is suggestive that at least in the Pacific region there is a low latitude generation of irregularities distinct from equatorial or auroral mechanisms. DTIC

IONOSPHERIC PHOTOELECTRONS MEASURED AT GEOSYNCHRONOUS ORBIT M.S. Thesis
John S. Laszakovits Jun. 1993 173 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272431) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Measurements of ions and electrons were made by the Los Alamos National Laboratory instrument, the Magnetospheric Plasma Analyzer, onboard spacecraft 1989-046. Observations from five days indicated the presence of both field aligned electrons and equatorially trapped electrons. Correlation existed between occurrences and location in the magnetosphere. Field aligned electrons were measured in the plasmasphere during daylight. On two days, field aligned electrons were also noted in the midnight region of the magnetosphere. Field aligned electrons at energies between

1 and 50 eV were characterized. These electron's spectrum were shown to be similar in shape to the ionospheric photoelectron distribution. Conic distributions of photoelectrons were observed between 08:00 and 10:00 local time on days when both photoelectrons and equatorially trapped electrons were present. V(sub parallel) versus V(sub perpendicular) spectrograms clearly indicated that photoelectrons undergo perpendicular acceleration. Lack of any magnetic field measurements or collection of wave data prevented determining the source of the acceleration. DTIC

ANALYSIS OF THE EFFECTS OF EURASIAN CRUSTAL AND UPPER MANTEL STRUCTURE ON REGIONAL PHASES USING BROADBAND SEISMIC DATA Final Report, Jul. 1990 - Mar. 1993
Jos Beckers, Susan Schwartz, and Thorne Lay 8 Jun. 1993 108 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-K-0041)
(AD-A272446; PL-TR-93-2131) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The results of the second phase of a two-year effort to investigate the effects of upper mantle structure on the propagation of regional phases are presented. The first year investigation was directed at improving our understanding of the behavior of the PP phase at upper mantle distances, and developing methods to map large-scale variations in uppermost mantle velocity structure. During the second year investigation, the techniques developed to a dataset of 45 PP waveforms for paths traversing China were successfully applied. A first order P wave velocity model for the crust and upper mantle under China, which best explains the overall dataset, was determined. Next, the data was investigated on a path-by-path basis to constrain lateral deviations from this average model and to map large-scale variations in absolute velocities and velocity gradients in the uppermost mantle under China. Our final effort was directed at exploring the effect of our regionalized velocity models, on the propagation of the P(sub n) and L(sub g) regional phases to assess how variations in the velocity structure under China influence P(sub n)/L(sub g) ratios for earthquakes and explosion sources. STANDARD ATMOSPHERES FOR ENGAGEMENT MODELING Final Report, Dec. 1991 - Nov. 1992
Ernest Bauer Jun. 1993 69 p
(Contract MDA903-89-C-0003)
(AD-A272447; IDA-D-1197; IDA/HQ-92-42146) Avail: CASI HC A04/MF A01

The use of model atmospheres for Ballistic Missile Defense (BMD) engagement modeling is reviewed. BMD engagement models simulate a ballistic missile attack from launch to interception. Model atmospheres are descriptions of atmospheric density and temperature as functions of altitude. However, BMD applications are not consistent in the choice of model atmosphere within a system application and, in fact, may employ more than one model atmosphere within an engagement model. The most widely used model atmospheres are the US-62 and US-76 models. These two differ significantly in the variable of solar activity. Thus, if engagement models run using both the US-62 and US-76 model atmospheres give the same result, the effect of the model atmosphere can probably be ruled out. It is recommended that to measure the effects of atmospheric variability on a particular BMD application, engagement models be run using both the US-62 and US-76 model atmospheres. If the results differ, more detailed examination of the physics of the atmosphere for the problem under consideration may be called for. DTIC

DETAILED ANALYSIS CASE STUDIES OF TRAPPED PLASMAS AT THE EARTH'S MAGNETIC EQUATOR M.S. Thesis
Eric S. Lantto Jun. 1993 154 p
(AD-A272497) Avail: CASI HC A08/MF A02

A previous statistical survey of data from the HPCE experiment on the AMPTE/CCE satellite established probability distributions for trapped ions and electrons. An extension of this survey for ions at 240 and 442 eV and for electrons at 340 and 770 eV confirmed these distributions. A further detailed analysis of the electron data from 13 individual data collection days also showed the trapped electron distribution to be concentrated in the dawn to noon region, centered at L=7. These trapped electron distributions can be described as a bi-Maxwellian distribution function and be characterized reasonably by the criteria that the flux has to exceed 5 x 10(exp 6) (sq cm s sr)(sup -1), the distribution has to be within 10 deg. of the magnetic equator, the ratio of the perpendicular temperature to the parallel temperature exceeds 3.0 and that the anisotropy exceeds 2.0 for 150 eV electrons and 4.4 for 340 eV electrons. Avail: CASI HC A03/MF A01; 3 functional color pages

Historically, cloud structures, dynamics, and precipitation processes have been observed and measured with sensors from two different spatial resolutions. Laser-based sensors have volume resolutions on the order of 10(exp -4) to 10(exp -2) cubic meters for a 1-s sample. Radar systems operating at wavelengths between 1 and 10 cm have resolutions on the order of 10(exp 4) to 10(exp 7) cubic meters. The resolutions of micro-wave systems depend primarily on the system RF bandwidth and antenna bandwidth. Both resolution regimes were useful in the study of cloud structures and processes - the former for determining resolution on the individual cloud particle scale and the latter for studying the coarse characteristics of cloud dynamics and structure. There are, however, cloud processes and structures that occur on scales that lie between these two regimes: the process of entrainment, where outside air is brought within the cloud boundaries; the mixing of in-cloud particles with different histories; cloud particle coalescence; and ice formation. The use of mm-wave (30- to 300-GHz) radars offers an opportunity to observe cloud processes at these scales and determine their influence on precipitation development, cloud albedos, cloud lifetimes, chemical cycling of tract substances, aircraft icing, and other meteorological phenomena. To determine the usefulness of a 35-GHz radar for observing these precipitation and cloud processes, a research program was initiated. The objectives of this program are to develop a 35-GHz radar, to measure scattering from precipitation and clouds, and to develop a model to compute scattering from clouds using the finite-difference time-domain (FDTD) technique. PHYSICS OF MAGNETOSPHERIC BOUNDARY LAYERS Semiannual Progress Report No. 1, 1 Jun. - 30 Nov. 1993
I. H. Cairns 20 Dec. 1993 6 p
(Grant NAGw-1483)
(NASA-CR-194725; NAS 1.26:194725) Avail: CASI HC A02/MF A01

The central ideas of this grant are that the magnetospheric boundary layers link disparate regions of the magnetosphere together, and the global behavior of the magnetosphere can be understood only by understanding the linking mechanisms. Accordingly the present grant includes simultaneous research on the global, meso-, and micro-scale physics of the magnetosphere and its boundary layers. These boundary layers include the bow shock, magnetosheath, the plasma sheet boundary layer, and the ionosphere. Analytic, numerical and simulation projects have been performed on these subjects, as well as comparison of theoretical results with observational data. Very good progress has been made, with four papers published or in press and two additional papers submitted for publication during the six month period 1 June - 30 November 1993. At least two projects are currently being written up. In addition, members of the group have given

papers at scientific meetings. The further structure of this report is as follows: section two contains brief accounts of research completed during the last six months, while section three describes the research projects intended for the grant's final period. Derived from text

ITERATIVE ELECTROMAGNETIC BORN INVERSION APPLIED TO EARTH CONDUCTIVITY IMAGING Ph.D. Thesis
D. L. Alumbaugh Aug. 1993 300 p
(Contract DE-AC03-76SF-00098)
(DE93-040668; LBL-34553) Avail: CASI HC A13/MF A03

This thesis investigates the use of a fast imaging technique to deduce the spatial conductivity distribution in the earth from low frequency (less than 1 MHz), cross well electromagnetic (EM) measurements. The theory embodied in this work is the extension of previous strategies and is based on the Born series approximation to solve both the forward and inverse problem. Nonlinear integral equations are employed to derive the series expansion which accounts for the scattered magnetic fields that are generated by inhomogeneities embedded in either a homogenous or a layered earth. A sinusoidally oscillating, vertically oriented magnetic dipole is employed as a source, and it is assumed that the scattering bodies are azimuthally symmetric about the source dipole axis. The use of this model geometry reduces the 3-D vector problem to a more manageable 2-D scalar form. The validity of the cross well EM method is tested by applying the imaging scheme to two sets of field data. Images of the data collected at the Devine, Texas test site show excellent correlation with the well logs. Unfortunately there is a drift error present in the data that limits the accuracy of the results. A more complete set of data collected at the Richmond field station in Richmond, California demonstrates that cross well EM can be successfully employed to monitor the position of an injected mass of salt water. Both the data and the resulting images clearly indicate the plume migrates toward the north-northwest. The plausibility of these conclusions is verified by applying the imaging code to synthetic data generated by a 3-D sheet model. DOE

POST-PALBOZOIC CRUSTAL RESPONSES TO THE CONTEMPORARY STRESS FIELD IN THE EASTERN UNITED STATES
W. P. Staub and H. K. Hardee Aug. 1993 7 p Presented at the 4th Energy Natural Phenomena Hazards Mitigation Conference, Atlanta, GA, 19-22 Oct. 1993
(Contract DE-AC05-84OR-21400)
(DE93-040604; CONF-9310102-17) Avail: CASI HC A02/MF A01

This paper summarizes the current state of knowledge with respect to post-Paleozoic tectonic features and their relationship to the contemporary stress field outside coastal plain regions of the eastern United States. Until the early 1970s, very little was known about such features. By the end of 1992 post-Paleozoic faults had been observed in at least five widely separated regions. Pleistocene-Holocene surface ruptures and liquefaction features had been observed over a steadily increasing area of the upper Mississippi embayment and adjacent regions. Ages of most recent ruptures on post-Paleozoic faults range from uncertain to Holocene and their senses of motion are compatible with the contemporary stress field. The cumulative amount of post-Paleozoic displacement on these faults is generally less than three meters. Fracture systems in Paleozoic rocks also are compatible with the contemporary stress field over a wide region of Indiana. DOE

During the past year, working groups of the committee have reviewed and reported on the status of regional networks, and wrote a report on the real-time warning of earthquakes. The field of seismology is going through revolutionary changes with new measurement capabilities, new analytical capabilities, and new understanding of earthquake processes at hand are still evolving. Earthquake 'gaps' are recognized as diagnostic elements for focusing on future large earthquakes; regional and national networks are under intense study, and future directions for them are emerging; and large scientific projects are under way in seismology which will bring new insights into earth structure, wave propagation, and earthquake processes. Ground motions and recurrence rates of earthquakes are major factors in the assessment of earthquake hazards, and improvements in both factors are badly needed. The Committee on Seismology will continue to review progress and needs for research on strong ground motions. DOE

MULTIORDER ETALON SOUNDER (MOES) DEVELOPMENT AND TEST FOR BALLOON EXPERIMENT Final Technical Report, 10 Jun. 1992 - 31 Dec. 1993
Paul B. Hays, Jinxue Wnag, and Jian Wu 14 Dec. 1993 38 p Original contains color illustrations
(Grant NAG8-919)
(NASA-CR-194730; NAS 1.26:194730) Avail: CASI HC A03/MF A01; 3 functional color pagaes

The Fabry-Perot interferometer (FPI), with its high throughput and high spectral resolution has been used in the remote-sensing measurements of the earth's atmospheric composition, winds, and temperatures. The most recent satellite instruments include the Fabry-Perot interferometer flown on the Dynamics Explorer-2 (DE-2), the High Resolution Doppler Imager (HRDI), and the Cryogenic Limb Array Etalon Spectrometer (CLAES) flown on the Upper Atmosphere Research Satellite (UARS). These instruments measure the Doppler line profiles of the emission and absorption of certain atmospheric species (such as atomic oxygen) in the visible and infrared spectral region. The successful space flight of DE-FPI, HRDI, and CLAES on UARS demonstrated the extremely high spectral resolution and ruggedness of the etalon system for the remote sensing of earth and planetary atmospheres. Recently, an innovative FPI focal plane detection technique called the Circle-to-Line Interferometer Optical (CLIO) system was invented at the Space Physics Research Laboratory. The CLIO simplifies the FPI focal plane detection process by converting the circular rings or fringes into a linear pattern similar to that produced by a conventional spectrometer, while retaining the throughput advantage of the etalon interferometer. The combination of FPI and CLIO allows the development of more sensitive Fabry-Perot interferometers in the infrared for the remote sensing of the lower atmospheres of Earth and possibly other planets. The Multiorder Etalon Sounder (MOES), a combination of the rugged etalon and the CLIO, compares very favorably to other space-borne optical instruments in terms of performance versus complexity. The new instrument is expected to be rugged, compact, and very suitable for an operational temperature and moisture sounder. With this technique, the contamination of radiance measurements by emissions of other gases is also minimized. At the Space Physics Research Laboratory (SPRL), the MOES concept and laboratory experiments were worked on for the past several years. Both theoretical studies and laboratory prototype experiments showed that MOES is very competitive compared with other high resolution sounders in terms of complexity and performance and has great potential as a compact and rugged high resolution atmospheric temperature and trace species sounder from the polar platform or the geostationary platform. The logical next step is to convert our laboratory prototype to a balloon instrument, so that field test of MOES can be carried out to prove the feasibility and capability of this new technology. Some of the activities related to the development of MOES for a possible balloon flight demonstration are described. Those research activities include the imaging quality study on the CLIO, the design and construction of a MOES laboratory prototype, the test and calibration of the MOES prototype, and the design of the balloon flight gondola. AREALLY AVERAGED ESTIMATES OF SURFACE HEAT FLUX FROM ARM FIELD STUDIES
R. L. Coulter, T. J. Martin, and D. R. Cook 1993 9 p Presented at the 3rd ARM Science Team Meeting, Norman, OK, 1-5 Mar. 1993
(Contract W-31-109-eng-38)
(DE93-018569; ANL/ER/CP-79787; CONF-9303122-6) Avail: CASI HC A02/MF A01

The determination of areally averaged surface fluxes is a problem of fundamental interest to the Atmospheric Radiation Measurement (ARM) program. The Cloud And Radiation Testbed (CART) sites central to the

ARM program will provide high-quality data for input to and verification of General Circulation Models (GCM's). The extension of several point measurements of surface fluxes within the heterogeneous CART sites to an accurate representation of the areally averaged surface fluxes is not straightforward. Two field studies designed to investigate these problems, implemented by ARM science team members, took place near Boardman, Oregon, during June of 1991 and 1992. The site was chosen to provide strong contrasts in surface moisture while minimizing the differences in topography. The region consists of a substantial dry steppe (desert) upwind of an extensive area of heavily irrigated farm land, 15 km in width and divided into 800-m-diameter circular fields in a close packed array, in which wheat, alfalfa, corn, or potatoes were grown. This region provides marked contrasts, not only on the scale of farm-desert (10-20 km) but also within the farm (0.1-1 km), because different crops transpire at different rates, and the pivoting irrigation arms provide an ever-changing pattern of heavy surface moisture throughout the farm area. This paper primarily discusses results from the 1992 field study. DOE

PROCEEDINGS OF THE WORKSHOP ON NEW GENERATION OF RADIATION BUDGET MEASUREMENTS FROM SPACE AND THEIR USE IN CLIMATE MODELLING AND DIAGNOSTIC STUDIES
L. Duemenil, ed. and E. Raschke, ed. (GKSS-Forschungszentrum Geesthacht, Germany.) Sep. 1992 34 p Workshop held in Hamburg, Germany, 11 Jun. 1992 Original contains color illustrations
(MPIM-90; ETN-94-93802) Avail: CASI HC A03/MF A01

Abstracts of papers presented at this workshop, whose aim was to bring together the research teams that are involved in the provision of satellite data from the ScaRaB (Scanner for Radiation Budget) project and potential users of these data in the climate modeling community, are presented. A continuation of spaceborne measurements of the planetary radiation budget is required in order to investigate the role of clouds and radiation within the climate system. Highly accurate measurements provided by the American ERBE (Earth Radiation Budget Experiment, 1984-1987) have proven to be excellent tools for the validation of climate model simulations. Experience gained with this data set is reported. It is proposed to employ a new radiation budget instrument, Scarab, to continue the monitoring of the required quantities from 1993 onwards. For individual titles, see N94-22284 through N94-22291.

SATELLITE MEASUREMENTS OF RADIATION BUDGET PARAMETERS
E. Raschke *In* Max-Planck-Inst. fuer Meteorologie, Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 3-6 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

The uses of the Scarab (Scanner for Radiation Budget, to be launched on the Soviet Meteor 3 satellite) data outside the diagnostics of the Earth's radiation budget and its temporal changes, for example to inspect possible variation and trends in the Earth's climate system, are considered. Historical remarks about means of measurement and analyses of the Earth's radiative energy exchange with space are given and sampling problems are considered. The need for further measurements of the planetary radiation budget with Scarab, despite the fact that basic spectral data sets collected within the ISCCP (International Satellite Cloud Climatology Project) are available, is explained. A summary of the relative partition of energy fluxes in the climate system, when the Sun is the only source, is given. ESA

ScaRaB AND ITS SUBSYSTEMS
Johannes Mueller *In* Max-Planck-Inst. fuer Meteorologie, Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 7-12 (For primary document see N94-22283 05-46)
Avail: CASI HC A02/MF A01

The technical aspects of the ScaRaB (Scanner for Radiation Budget) radiometer to be launched on the Soviet Meteor 3 satellite are described. The instrument measures the radiance at the top of atmosphere in four channels (visible, solar, total, atmospheric window). The resolution is 48 by 48 mrad. Lamps and blackbodies are used for onboard calibration. These sources are calibrated themselves on ground before launch. ESA

THE USE OF ERBE DATA FOR CLIMATE STUDIES **c47**
R. Stuhlmann and M. Rieland (Deutscher Bundestag, Bonn, Germany.) *In* Max-Planck-Inst. fuer Meteorologie, Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 13-18 (For primary document see N94-22283 05-46)
Avail: CASI HC A02/MF A01

The contribution of clouds to the shortwave radiation budget is discussed. In order to do this the concept of 'cloud radiative forcing' is applied to different satellite data sets to estimate the cloud forcing on the absorbed shortwave radiation at the top of the atmosphere, the surface, and within the atmosphere itself. All calculations for the top of the atmosphere are based entirely on measurements of the Earth Radiation Budget Experiment (ERBE). For the radiation budget at the surface, the incoming solar radiation at the surface is derived from Meteosat data and the surface albedo is calculated from ERBE clear sky planetary albedo measurements by applying an atmospheric correction scheme. The results are summarized. The dependence of cloud forcing on different cloud types, characterized by low, middle, and high level clouds, was investigated. The global shortwave radiation budget was assessed and results are summarized. ESA

SATELLITE VALIDATION OF GCM-SIMULATED ANNUAL CYCLE OF THE EARTH RADIATION BUDGET AND CLOUD FORCING
Sandrine Bony, Herve LeTreut, Jean-Philippe Duvel (Ecole Polytechnique, Palaiseau, France.), and Robert S. Kandel (Ecole Polytechnique, Palaiseau, France.) *In* Max-Planck-Inst. fuer Meteorologie, Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 19-20 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

Earth Radiation Budget Experiment (ERBE) data are used to validate radiative fluxes and cloud radiative forcing simulated by the general circulation model (GCM). Regional and zonal distribution of actual and clear sky fluxes are considered to validate the general description of the earth radiation budget of the model. Tests to get more significant elements of comparison between models and observations are developed. These tests are applied to the actual radiation budget, to the clear sky fluxes, and to the cloud radiative forcing (CRF). ESA

THE SEASONAL VARIATION OF THE CLOUD RADIATIVE FORCING: COMPARISON OF ECHAM MODEL SIMULATIONS WITH ERBE DATA
Erich Roeckner *In its* Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 21-24 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

The third generation atmospheric general circulation model ECHAM3, which was developed from an earlier version of the European Centre for Medium Range Weather Forecasts (ECMWF) medium range weather forecast model, is used for studying the impact of clouds on the radiation budget at the top of the atmosphere. The model was forced with observed sea surface temperatures between 1979 and 1988 so that there is a four year overlap with Earth Radiation Budget Experiment (ERBE) data (1985-1988). Results are presented for one year (Feb. 1985 - Jan. 1986) for which scanner measurements made by the ERBE and NOAA 9 satellites are available. It is shown that there is generally good agreement between the simulated and observed zonal mean cloud forcing for 1985. The seasonal variation of the zonal mean errors of the cloud forcing for 1985 are shown and discussed. The ERBE data can also be used to study the cloud variations due to internal temperature variations such as the El Nino southern oscillation cycle (ENSO) or the seasonal cycle. The response of the cloud forcing to seasonal temperature variations for July 1985 is shown. ESA

N94-22289# Max-Planck-Inst. fuer Meteorologie, Hamburg (Germany).
USE OF SATELLITE DATA FOR VALIDATION OF THE ECHAM MODELS
K. Arpe *In its* Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use on Climate Modelling and Diagnostic Studies Sep. 1992 p 25 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

The validation of the ECHAM3 models, which are intended for use in simulating future climates, is considered. It is no longer sufficient to simply compare climatological means; the interannual variability also has to be investigated. In order to do this the impact of sea surface temperatures (SST) on the interannual variability in the model was investigated by running several experiments with different initial states but with the same observed SST. Results are given. The plan to use observation satellites to investigate this further is discussed. The use of geostationary satellites to provide information about the diurnal cycle is also considered. The use of satellite observations should give indications of changes in the albedo due to the aging of snow. ESA

SIMULATION OF CLEAR-SKY OUTGOING LONGWAVE RADIATION OVER THE OCEANS USING OPERATIONAL ANALYSIS **c47**
A. Slingo and M. J. Webb *In its* Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 26-28 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

A system for the simulation and analysis of measurements from satellites using operational analyses (SAMSON) was developed. Simulations of clear sky outgoing longwave radiation (OLR) over the oceans are compared with data from the Earth Radiation Budget Experiment (ERBE). The calculations were performed with a Malkmus narrow band radiation scheme, including the effects of all the radiatively important gases. Sea surface temperatures were taken from the United Kingdom National Meteorological Center's blended analyses, and ozone data from the Nimbus 7 Solar Backscatter Ultraviolet experiment. Atmospheric temperatures and humidities came from operational analyses. Parallel simulations were performed with the analyses produced both by the European Center for Medium Range Weather Forecasts (ECMWF) and by the United Kingdom Meteorological Office (UKMO). Simulations for the period Feb. 1985 - Oct. 1986 were compared with ERBE data. ESA

N94-22291# European Centre for Medium-Range Weather Forecasts, Reading (England).
USE OF SATELLITE DATA FOR VALIDATION OF OPERATIONAL FORECAST MODELS AND OPERATIONAL ANALYSES **c47**
E. Klinker *In* Max-Planck-Inst. fuer Meteorologie, Proceedings of the Workshop on New Generation of Radiation Budget Measurements From Space and Their Use in Climate Modelling and Diagnostic Studies Sep. 1992 p 29 (For primary document see N94-22283 05-46)
Avail: CASI HC A01/MF A01

At the European Center for Medium Range Weather Forecasts (ECMWF), the operational forecast fluxes of radiation at the top of the atmosphere are monitored by comparing zonal and monthly means to the appropriate part of a fixed annual cycle of Earth Radiation Budget Experiment (ERBE) fluxes averaged in the same way. Some information on the general performance of the forecast model characteristics can be gained from scatter diagrams; one useful example is a scatter diagram of the greenhouse function over sea surface temperature. A synchronous comparison of ERBE and model fluxes for periods more than one to two years ago is only of limited use for the validation of the present model formulation. At ECMWF the data assimilation was repeated for a period when a good coverage of satellite data was available (Jul. and Aug. 1987). By using the model and analysis formulation of Jul. 1991 it was possible to evaluate the more recent changes in the parameterization of cloud radiation interaction. The synchronous comparison allows the validation of single circulation systems like the extra tropical cyclones, tropical cloud cluster, or tropical easterly waves. Additionally a comparison of observed and predicted monthly means and standard deviations of daily values give a good indication where the cloud-radiation interaction is still unsatisfactory. ESA

VECTOR GRAVIMETRY BY A COMBINATION OF INERTIAL AND GPS SATELLITE MEASUREMENTS Ph.D. Thesis
Elfriede T. Knickmeyer Sep. 1990 173 p
(ISBN-0-315-61980-5; CTN-94-60892) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Vector gravimetry with inertial navigation systems (INS) has been successfully performed in semi-kinematic mode for several years. With advances in the kinematic use of the Global Positioning System (GPS), kinematic vector gravimetry has also come within reach. The problems of reducing the effect of INS sensor errors, determining the kinematic acceleration by means of GPS observations, and modelling the gravity vector in a state space setting are addressed. The requirements on INS and GPS observations are investigated in a covariance analysis. Different INS mechanizations, strapdown, platform, and rotating sensor unit are compared. It is shown that only the last two are suited for vector gravimetry. Subject to the principal limitations of the simulation study, the quantitative results show that current INS and GPS hardware should allow the determination of deflections of the vertical with an accuracy of 1 arcsecond. The determination of gravity anomalies with an accuracy of 10 micrometers per second squared, however, imposes very stringent requirements on the determination of the kinematic acceleration with GPS, which may possibly be met by high data rates and extensive filtering. A COMPARISON OF A SIMPLE MODEL OF EUV DAYGLOW WITH VIKING DATA M.S. Thesis
Maurice Thomas Shevalier Feb. 1993 110 p
(ISBN-0-315-83258-4; CTN-94-60940) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A simple model of extreme ultraviolet dayglow was developed to determine the origin of double limbs observed by the Swedish Viking satellite, which had five instruments designed to investigate different regions of the auroral processes. A simple model was developed using results from previously published models. The shape and intensities of the calculated profiles match those that appear in the literature. The Viking altitude/intensity profiles show two peaks present which do not match published or modelled profiles. When the altitude of the upper peak was adjusted to match the modelled peak, the lower peak was decreased in altitude from 120 to 9 km, indicating a possible tropospheric source for the lower peak. The volume emission rate profiles obtained from the model and from altitude corrected inverted Viking data were very similar. The modelled column intensities were significantly larger than the Viking satellite's, so the normalized peak intensities were compared. The peaks have a similar shape with differences attributed to long wavelength leakage in the camera. Author (CISTI)

IMPLICATIONS OF VIKING DAYSIDE AURORAL MEASUREMENTS Ph.D. Thesis
Vo Hienbich Sep. 1992 293 p
(ISBN-0-315-83273-8; CTN-94-60941) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The ultraviolet images and other supporting data obtained by the Viking satellite were used to determine the general characteristics of dayside aurora. After defining a localized intensification in the auroral images, a statistical survey was made from a data set consisting of 60 Viking passes. Results indicate that the most probable region in which such features were found was 14-16 magnetic local time (MLT); this region often consists of more than one feature which have a spatial periodicity of 0.4 or 0.7 MLT. The source of the afternoon aurora was determined to be the low latitude boundary layer and colocated within a convection reversal region. Dayside aurora was determined to be a conjugate phenomenon which implied they are located on closed field lines. A strong dependence on the solar wind velocity was found for the active cases. All of this evidence suggests that afternoon auroras are caused by the Kelvin Helmholtz instability acting on the flank of the magnetosphere, as illustrated in a magnetosphere ionosphere coupling model. The results indicate that this viscous process

could play a main role in the interaction between the solar wind and the magnetosphere. Author (CISTI)

AN ANALYSIS OF CLOUD-COVER REPORTING IN THE 1977 SURFACE OBSERVATION DATABASE

James G. Saccomando, Jr. Sep. 1993 14 p

(AD-A271102; USAFETAC/PR-93/002) Avail: CASI HC A03/MF A01

This document describes an analysis of the Air Force climatological surface weather observation database to determine global coverage and frequency of cloud-cover reports during the year 1977. The results of the analysis are depicted by cloud-cover reporting coverage and frequency plotted on global maps. DTIC

CLOUDS: THEIR PREDICTION AND SIMULATION Annual Technical Report, 1 Apr. 1992 - 31 May 1993

W. R. Cotton and G. L. Stephens 30 Jun. 1993 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Grant AF-AFOSR-0269-91)

(AD-A271161; AFOSR-93-0790TR) Avail: CASI HC A03

Mesoscale forecasts of several FIRE 2 cirrus events have been repeated using newly developed microphysics schemes. Boundary layer cloud fractional coverage schemes has been tested for one of the FIRE 1 stratocumulus cases in which there was a transition from solid stratocumulus to broken cumuli. RAMS ability to simulate ordinary deep convective clouds has been evaluated for one of the CaPE cases over the Kennedy Space Flight Center. New modules for cloud microphysics and radiation transfer have been written and the impacts of those schemes on cloud forecasting will be evaluated in the future. DTIC

WORLDWIDE FREQUENCY OF TEMPERATURES AT SELECTED ALTITUDES

James G. Saccomando, Jr. Sep. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A271111; USAFETAC/PR-93/003) Avail: CASI HC A03

This report provides maps that give frequency of occurrence of temperatures less than or equal to certain values at selected altitudes worldwide. Monthly data is plotted on world maps, with contours of probability. The analysis was performed using the Air Force Global Weather Central's HIRAS (High-Resolution Analysis) temperature and D-value data for 1985-1991. The analysis was accomplished for a 2.5 by 2.5 degree latitude/longitude global grid. The results of the analysis appear consistent with what meteorologists know about the atmosphere. The maps show USAFETAC's recently acquired data visualization capabilities. DTIC

PREDICTING LIGHTNING EVENTS IN THE KSC AREA: A FEASIBILITY STUDY USING SINGLE STATION DATA Interim Report

Robert O. Berthel 8 Dec. 1992 32 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AF Proj. 6670)

(AD-A271440; PL-TR-92-2333; ERP-1114) Avail: CASI HC A03

Surface observations and early-morning radiosonde measurements, taken on a regular daily basis in the KSC area during a late summer period, were scrutinized in an effort to form a correlation with subsequent lightning-related activity. Wind directions were the only measurements that could be directly associated. This study revealed that lightning activity, other than that associated with large-scale storm systems, developed in the 12-hr period following the morning radiosonde when both surface and upper-air (averaged between the 600-800 mb pressure levels) winds had directions that brought air off the ocean and moved it over lands towards KSC. The most basic explanation is the advection of oceanic water vapor, the elevation of the moisture through convergence and the transport of that moisture to KSC by upper-air winds. This premise was supported by the evidence of days having no lightning activity, presumably caused by the lack of advection and/or convergence or from elevated moisture being carried away from KSC. This investigation concludes that there is a good probability that the occurrence of daytime-lightning-related activity, local to the general KSC area, may be predicted from knowledge of the late-night to early-morning surface and upper wind directions. MESO-BETA SCALE NUMERICAL SIMULATION STUDIES OF TERRAIN-INDUCED JET STREAK MASS/MOMENTUM PERTURBATIONS Semiannual Report

Yuh-Lang Lin and Michael L. Kaplan Nov. 1993 121 p

(Grant NAG5-1790)

(NASA-CR-194627; NAS 1.26:194627) Avail: CASI HC A06/MF A02

The Control-B simulation experiment was designed to improve on the Control-A experiment performed with the GMASS model. This experiment addressed several inadequacies with the first smooth terrain numerical simulation by including: (1) increased nested-grid resolution to better define the simulated gravity waves, (2) increased horizontal diffusion to remove outflow boundary condition noise, and (3) the use of reanalyzed rawinsonde data and surface observations in the initial state to increase the definition of the observed jet streak as well as other low-level features. A smoothed-terrain dry simulation with the nested-grid GMASS model has revealed many important aspects of the processes which resulted in the generation of gravity waves in the region and time when and where they were observed. However, the vertical structure, number, and characteristics of the waves are still quite different from observed waves as diagnosed thus necessitating future improved simulations. However, this control simulation has produced substantial insight into processes which occur on many spatial scales over a 30 hour time period thus allowing one to draw promising inferences as to the mechanisms for the complex process which occurred in nature during the CCOPE case study. The theoretical aspects of the project have focus on understanding the nature of the ageostrophic circulations which are produced in idealized models of the atmosphere in which the troposphere is modeled in one of two ways. The first model assumes that the lower atmosphere can be represented as a single layer of homogeneous fluid whose upper surface is free to exhibit vertical displacement. Two-dimensional internal convergence (divergence) occurring during the adjustment to an asymptotic equilibrium state from an ageostrophic initial state whose momentum structure is representative of a midlatitude localized zonal wind anomaly will cause the free upper surface of the homogeneous atmosphere to rise (fall), and therefore the response can be viewed as being physically three-dimensional. The second model assumes that the troposphere can be represented by an unbounded continuously stratified Boussinesq fluid of constant Brunt-Vaisala frequency N, where the vertical gradient of the basic state potential temperature profile allows for the existence of vertically propagating internal inertia-gravity waves.

THE MARINE LIGHT-MIXED LAYER EXPERIMENT CRUISE AND DATA REPORT: R/V ENDEAVOR CRUISE EN-224, MOORING DEPLOYMENT, 27 APRIL-1 MAY 1991: CRUISE EN-227, MOORING RECOVERY, 5-23 SEPTEMBER 1991

Albert J. Plueddemann, Robert A. Weller, Thomas D. Dickey, John Marra, and George H. Tupper May 1993 125 p

(Contract N00014-89-J-1683)

(AD-A271175; WHOI-93-33; UOP-93-4) Avail: CASI HC A06/MF A02

The Marine Light-Mixed Layer experiment took place in the sub-Arctic North Atlantic ocean, approximately 275 miles south of Reykjavik, Iceland. The field program included a central surface mooring to document the temporal evolution of physical, biological, and optical properties. The surface mooring was deployed at approximately 59 deg N, 21 deg W on 29 April 1991 and recovered on 6 September 1991. The Upper Ocean Processes Group of the Woods Hole Oceanographic Institution was responsible for design, preparation, deployment, and recovery of the mooring. The Group's contribution to the field measurements included four different types of sensors: a meteorological observation package on the surface buoy, a string of 15 temperature sensors along the mooring line, an acoustic Doppler current profiler, and four instruments for measuring mooring tension and accelerations. The observations obtained from the mooring are sufficient to describe the air-sea fluxes and the local physical response to surface

forcing. The objective in the analysis phase will be to determine the factors controlling this physical response and to work towards an understanding of the links among physical, biological, and optical processes. This report describes the deployment and recovery of the mooring, the meteorological data, and the subsurface temperature and current data. DTIC

ANALYSIS OF WIND OBSERVATION FROM TOWERS IN THE PERIOD 1977-1991 [ANALYSE VAN TORENWINDGEGEVENS OVER HET TIJDVAK 1977 TOT EN MET 1991]
Gertie Geertsema 1992 31 p In DUTCH
(KNMI-TR-148; ISBN-90-369-2027-2; ETN-94-94533) Avail: Issuing Activity (Royal Netherlands Meteorological Institute, Postbus 201, 3730 AE De Bilt, Netherlands)

Wind measurements performed on television broadcasting towers up to a height of about 200 m are analyzed with a view to meteorological support in case of calamities, such as the accidental release of radioactive or chemical substances. The emphasis is on the wind velocity. The error of the estimated wind direction depends strongly on the wind velocity. The error of the wind velocity can be significant. The mixing height is an important parameter in the distribution of air pollution. The choice of the wind direction measuring location is very important. ESA

THE LIFE CYCLES OF INTENSE CYCLONIC AND ANTICYCLONIC CIRCULATION SYSTEMS OBSERVED OVER OCEANS Semiannual Status Report, 1 Jul. - 31 Dec. 1993
Phillip J. Smith 31 Dec. 1993 12 p
(Grant NAG8-915)
(NASA-CR-194760; NAS 1.26:194760) Avail: CASI HC A03/MF A01

Full attention was now directed to the blocking case studies mentioned in previous reports. Coding and initial computational tests were completed for a North Atlantic blocking case that occurred in late October/early November 1985 and an upstream cyclone that developed rapidly 24 hours before block onset. This work is the subject of two papers accepted for presentation at the International Symposium on the Lifecycles of Extratropical Cyclones in Bergen, Norway, 27 June - 1 July 1994. This effort is currently highlighted by two features. The first is the extension of the Zwack-Okossi equation, originally formulated for the diagnosis of surface wave development, for application at any pressure level. The second is the separation of the basic large-scale analysis fields into synoptic-scale and planetary-scale components, using a two-dimensional Shapiro filter, and the corresponding partitioning of the Zwack-Okossi equation into synoptic-scale, planetary-scale, and synoptic/planetary-scale interaction terms. Preliminary tests suggest substantial contribution from the synoptic-scale and interaction terms. Author (revised)

Understanding tropical cyclone (TC) intensification is a problem that continues to intrigue researchers and forecasters. The objective of this case study was to investigate, by examination of the fields from a numerical model and satellite rain rate observation, the following: (1) the relationship between TC precipitation and intensity changes; and (2) the relationship between spatial and temporal changes in a TC's precipitation and large scale environmental tropospheric forcing. A study whose aim was to implement an Offshore Decision Support system (ODS) for offshore operations is reported. The ODS needs easy access to wind wave and current forecasts, for which an offshore data storage and retrieval system will be installed. The ODS will be tested during actual offshore operations for a duration of 4 weeks in a period of 8 months. For periods in the operational phase of the project, wave hindcasts were generated with the help of a third generation wave model using data assimilation (WAVEWATCH subtask). During the evaluation, these results were compared with the standard forecasts used in the project. In this way, the impact of ERS-1 data to improve the safety of offshore operations was assessed. THE ANALYSIS OF GLOBAL CLOUD AND RADIATION DATA FOR THE STUDY OF CLOUD-CLIMATE INTERACTIONS Annual Report, 1 Jan. - 31 Dec. 1993
Harshvardhan 1993 41 p Proposed for presentation at the Eighth AMS Radiation Conference, Nashville, TN, Jan. 1994 Submitted for publication
(Grant NAGw-3150)
(NASA-CR-193388; NAS 1.26:193388) Avail: CASI HC A03/MF A01

During the past year, ISCCP C1 data has been analyzed for two regions,

the stratocumulus area off California and the tropical Atlantic. The first part of the study dealing with stratocumulus clouds is complete and the results form the technical portion of this report. A manuscript that has recently been prepared covering this subject is attached as an Appendix. The abstract describes the key finding that cloudy mean liquid water path (LWP) is invariant with cloud fraction for cloud cover between 20% - 80%. Similar conclusions are reached with ISCCP and LANDSAT data. This has important implications for General Circulation Models. A possible application is described in the Discussion section of the Appendix. An idea that has been proposed for dealing with GCM hydrology can be used.

LOW-ALTITUDE CROSS-WIND VELOCITY MEASUREMENTS USING PULSED VISIBLE FRINGE-TYPE LASER ANEMOMETRY

Eckhardt W. Sommer and Hans J. Pfeifer Jun. 1992 9 p Presented at the SPIE International Symposium and Exhibition on Optical Engineering and Photonics, Orlando, FL, 22-24 Apr. 1992 Sponsored by Ministry of Defence, Germany

(ISL-CO-216/92; ETN-94-95125) Avail: Issuing Activity (Fachinformationszentrum Karlsruhe, 7514 Eggenstein-Leopoldshafen 2, Germany)

A pulsed fringe type laser Doppler anemometer was developed during a feasibility study for remote wind velocity measurements. In contrast to conventional Doppler systems, this technique directly measures the cross components of the wind vector. Field measurements over a range of 100 m demonstrated successfully the performance of this method and showed eventual restricting atmospheric conditions. ESA

OPTICAL CLIMATOLOGY OF THE NORTHEAST PACIFIC OCEAN Final Report

James L. Mueller 3 Mar. 1993 127 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contracts N00014-87-C-6002; N00014-89-C-6007; DA Proj. R12-99) (AD-A271671; CHORS-001-93; NRL-CR/7410-93-0004) Avail: CASI HC A07

This report describes the results of a climatological study of optical variability in the upper 200 m of the Northeast Pacific Ocean. This work was supported by the Oceanographer of the Navy under NORDA/NOARL contracts N00014-87-C-6002 (SIO Visibility Lab., UCSD, La Jolla, CA) and N00014-89-C-6007 (SDSU CHORS, San Diego, CA), and this document constitutes our Final Report under those contracts. The project addressed two primary objectives. The first objective was to describe the two-dimensional spatial distribution and temporal variability of near-surface biooptical properties derived from satellite ocean color imagery, and to deliver the results in the form of a data base suitable for the developing new environmental products to support naval applications in the region. The second objective was to develop a model, with which the near-surface bio-optical properties derived from satellite data can be extrapolated downward to depths of interest for naval operations (i.e. 200 m). WEATHER TUTOR 1: STABILITY BASICS Interactive Training Package

Aug. 1993 19 p

(AD-A270758; AWS/ITP-93/001) Avail: CASI HC A03/MF A01

This is the first in a series of computer-based interactive packages produced by Air Weather Service for use by Air Force weather units. It consists of text (instructions for running and using the computer program) and three 3 1/2-inch diskettes containing program software that generate high-resolution graphic images, animation, and text. The training package is in three parts: the first familiarizes students with the relationships between atmospheric variables; the second correlates these variables to atmospheric stability using the parcel theory and the Equation of State; and the third and final part demonstrates the relationships of stability and moisture content with corresponding cloud scenes. An entry knowledge test is required before starting the lesson. DTIC

HYDROSTATIC/NONHYDROSTATIC COMPARISON WITH THE MERCURE CODE ON OROGRAPHIC FLOWS Ph.D. Thesis [COMPARAISON HYDROSTATIQUE/NON HYDROSTATIQUE AVEC LE CODE MERCURE SUR LES ECOULEMENTS OROGRAPHIQUES]

Ahmed Elkhalfi 1992 170 p In FRENCH

(ETN-93-94603) Avail: CASI HC A08/MF A02

A study of meteorologic flows over complex reliefs using the MERCURE model is reported. The analytic solution to the problem of simple mountain waves was first examined by finding out which conditions the models was capable of reproducing, and then nonlinear, and finally cases near to observation were examined. The equations used in the MERCURE model are presented. Different existing versions of the code were assembled into one single code and the use of the space memory and speed of calculation were improved. To avoid precision problems posed by the advection stage by the method of applied characteristics in cases of slight relief, a more simple schema of the advection type 'Euler backward' was developed, which enabled the validation of the model to be carried out on linear solutions of mountain waves. The numerical performance of the code during the three dimensional resolution of the pressure was improved. Besides the nonhydrostatic resolution of the pressure which already existed, a hydrostatic resolution was developed on the same version of the code MERCURE. This enabled the model to be used in the hydrostatic regime, as well as to address the convergence problems of the solver of pressure linked to the grid distortion. The two resolutions were compared for the simulation of flow over complex reliefs. The model was then applied to academic cases and finally to real situations. ESA

(Contract F49620-92-J-0193)

(AD-A271672; CASS-93-3-01; AFOSR-93-0825TR) Avail: CASI HC A14

In this report, further analyses of data taken during the Arecibo Initiative in Dynamics of the Atmosphere (AIDA'89) campaigns are presented, concentrating on the third campaign (Scene III) from May 2-9, 1989. The major emphasis is on the comparison between the MAPSTAR Imaging Doppler Interferometry (IDI) radar and the Arecibo Observatory incoherent scatter (ISR) radar, but some comparisons with the Geospace Corporation meteor wind radar (MWR) and the Arecibo Observatory Fabry-Perot spectrometer (FPS) are also included. A re-analysis of four IDI - ISR - MWR comparisons show better agreement between all three techniques than previously reported. In general, better agreement was found between the daytime radar winds than that previously published for the April campaign, with the zonal winds agreeing better than the meridional. In contrast, the nighttime IDI - FPS comparisons showed better agreement in the meridional component and considerably better agreement after midnight than before.

HOLOGRAPHIC MEASUREMENTS OF ICE CRYSTALS IN CIRRUS CLOUDS DURING INTERNATIONAL CIRRUS EXPERIMENT ICE Thesis - Cologne Univ. [HOLOGRAPHISCHE MESSUNGEN AN EISKRISTALLEN IN CIRRUSWOLKEN WAEHREND DES INTERNATIONALEN CIRRUS EXPERIMENTS ICE]

C. Krupp 31 Jan. 1992 144 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(GKSS-92/E/14; ETN-93-94185) Copyright Avail: CASI HC A07

An airborne holographic system is described. The system was employed during the International Cirrus Experiment in 1989. Ice particle concentration, size and shape were determined in three height levels in cirrus clouds and assigned to the surrounding temperature and humidity. Most of the particles were found to be smaller than 100 micrometers. Hexagonal columns, bullets, particles of irregular shape, and only a few hexagonal plates were detected. Nearly all particles larger than 200 micrometers showed a complex internal structure. Most of them were bullet rosettes and combinations of columns. Only one rimed column and one frozen big drop were found in the sampled data. The limitations and uncertainties of the holographic system were investigated and proposals for improvements are made. An improved system would be able to collect images of particles as small as 20 micrometers and determine their concentration and size. The development of a proposed new holographic system should be able to detect particles as small as 8 micrometers. The very labor intensive data extraction process outlines the need for the development of an automatic image analyzing system, which is also discussed. ESA

SIMULATED REAL-TIME INTERCOMPARISON OF HYDROLOGICAL MODELS
1992 256 p
(WMO-779; OHR-38; ISBN-9-26-310779-3; ETN-93-94843) Copyright
Avail: CASI MF A03; print copy available from WMO, Geneva, Switzerland

A study to compare the abilities of both rainfall runoff and snowmelt runoff models to forecast streamflow under simulated real time conditions is presented. The results of the study are reported, thus offering guidance through demonstrations of the models' abilities in various situations. Case studies from operators of real time hydrologic forecasting systems are reported, thus permitting inclusion of actual operational experiences not contained in the simulated real time exercise. The material prepared was disseminated to interested countries in order to encourage the adoption of such approaches to forecasting runoff and to assist countries that plan to use models for forecasting. INCORPORATION AND COMPARATIVE EVALUATION OF A NON-CONVECTIVE CLOUD PARAMETERIZATION SCHEME IN THE NAVAL RESEARCH LABORATORY WEST COAST MESOSCALE WEATHER PREDICTION MODEL M.S. Thesis
Damacene V. Ferandez Jun. 1993 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A272417) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study describes the incorporation of the Sundqvist et al. (1989) explicit non-convective cloud liquid water scheme into the Naval Research Laboratory (NRL) limited area dynamical weather prediction model. Comparisons were made between model runs with the non-convective cloud water scheme and those without the scheme to evaluate mesoscale wind pattern, longwave radiation, temperature, and cloud simulations over the U.S. West Coast for the time period 0000 UTC 02 May 1990 to 1200 UTC 03 May 1990. The most significant improvement in the updated model was the more physically realistic horizontal and vertical non-convective cloud structures produced by the cloud liquid water fields. DTIC

A RETRIEVAL ERROR ANALYSIS TECHNIQUE FOR PASSIVE INFRARED ATMOSPHERIC SOUNDERS Technical Report
John P. Kerekes 8 Jul. 1993 50 p
(Contract F19628-90-C-0002)
(AD-A272618; TR-978; ESC-TR-92-204) Avail: CASI HC A03/MF A01

To support the design and analysis of passive infrared atmospheric sounding instruments, an analytical error analysis technique has been implemented. This technique is based on a linear approximation to the radiative transfer equation and uses a minimum variance estimation approach to atmospheric profile retrieval. As a result, once the proper matrices have been constructed an estimate of the retrieval error is computed through a single linear matrix equation. The solution vector is written with temperature and water vapor explicitly defined, thus producing the error vector for both simultaneously. Examples showing typical results are presented for a high spectral resolution sounder as well as for a lower resolution, filter-wheel type of instrument. DTIC

ANALYSIS OF A SANDSTORM WEATHER PROCESS-TRANSLATION
Dongzhen Yang and Xiangming Ji 5 Nov. 1993 23 p Transl. into ENGLISH from Yici Huangsha Tianqi Guocheng Di Fenxi, Qixiang Xuebao Meteorology (China), v. 49, no. 3, Aug. 1991 p 334-342
(AD-A272959; FASTC-ID(RS)T-0331-93) Avail: CASI HC A03/MF A01

The favorable synoptic situation and climate background for a sandstorm process, which occurred in the period from the 9th to the 16th of April 1988, has been studied through analyzing weather maps, meteorological elements, satellite cloud pictures, and sandstorm trajectories. The sand dust origin area, the directions and the paths of sand dust transportation, and the extent the sand dust reached were also investigated. The results of measurements and analysis indicate that the concentration of sand dust particles is ten times greater than the normal. It is also shown that the elements in the sand dust are lithophile and come from natural source through the chemical composition analysis of the sand dust, so that the sand dust has not been seriously polluted by human activities. LARGE-SCALE CIRCULATION REGIMES AND TROPICAL CYCLONE CHARACTERISTICS OVER THE WESTERN PACIFIC OCEAN Ph.D. Thesis
Patrick A. Harr Jun. 1993 300 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A273004) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The basic structure of the variability of the large-scale circulations over the tropical western North Pacific is investigated with respect to its influence on tropical cyclone characteristics. A vector empirical orthogonal function analysis and a fuzzy cluster algorithm are used to define six recurrent 700 mb circulation patterns that represent large-scale variabilities associated with the monsoon trough and subtropical ridge. Three circulation patterns are associated with an active monsoon trough, and two patterns represent an inactive monsoon trough. One pattern depicts small deviations from the long-term climatology. The 700 mb circulation patterns are shown to be physically consistent with outgoing longwave radiation anomalies and the 200 mb stream function and velocity potential anomalies. A seventh set of circulation patterns is defined to contain transition periods between the active, inactive, and small anomaly patterns. Transitions between recurrent circulation patterns may be within the active or the inactive patterns, or be transitions across the active/inactive boundary that are associated with major circulation changes. These significant transitions occur over a very limited set of paths, which are shown to be associated with interactions among tropical and midlatitude circulation systems. The recurrent circulation patterns and their transitions are shown to explain much of the observed intraseasonal variability in the occurrence and track types (recurving versus straight-moving) of tropical cyclones over the western North Pacific. COMPUTERIZED SIMULATIONS WITH CELLULAR AUTOMATES FOR CLOUD FORMATION Thesis - Cologne Univ.
[COMPUTERSIMULATIONEN MIT ZELLULARAUTOMATEN FUER WOLKENBILDUNG]
K. Nagel 24 Feb. 1992 104 p In GERMAN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(GKSS-92/E/22; ETN-93-94187) Copyright Avail: CASI HC A06

Starting from the phenomenology of cloud formation, a cellular automaton simulation model of the process is derived. The model turns out to have a strong resemblance to percolation based growth models; percolation plays an important role in the theory of random fractals. Projections of thereby produced clusters show a realistic fractal dimension of the perimeter, but only at or near the critical percolation threshold P(sub c). A mechanism based on the continuity equation is proposed and numerically tested which possibly explains why the atmosphere acts in fact near its critical threshold during cloud formation (self organizing criticality). Numerically, this is achieved

by a feedback of the number of 'active' sites on the occupation concentration p. ESA

NOVAM EVALUATION UTILIZING ELECTRO-OPTICS AND METEOROLOGICAL DATA FROM KEY-90 Final Technical Report
S. G. Gathman, W. P. Hooper, J. E. James, H. E. Garber, and K. Davidson Sep. 1993 74 p
(AD-A271722; NRAD-TR-1608) Avail: CASI HC A04/MF A01

An experiment known as KEY-90 took place in the Straits of Florida, from 2 to 19 July 1990. The center of operations was the town of Marathon, which is in the center of the Florida Keys. The experiment's principal objective was to verify the Naval Oceanic Vertical Aerosol Model (NOVAM) and its kernel, the Navy Aerosol Model (NAM), in a tropical ocean scenario. The data collected during KEY-90 included aerosol particle-size distributions, lidar profiles, pertinent meteorological observations, and ocean surface parameters. Shore stations, a boat, buoys, radiosondes, and aircraft provided platforms to obtain these data. These measurements determined the structure of the atmospheric surface boundary layer. This report presents a general overview of these experiments, a description of the data available from KEY-90, and specific examples of these data for 14 July 1990. DTIC

DEVELOPMENT AND TESTS OF A CLOUD PHYSICS PARAMETERIZATION FOR REAL-TIME AVIATION AND PUBLIC NUMERICAL WEATHER FORECASTING
P. Schultz Apr. 1993 48 p
(PB93-202711; NOAA-TM-ERL-FSL-6) Avail: CASI HC A03/MF A01

A package of FORTRAN subroutines for parameterizing condensation and precipitation processes in mesoscale models is described. The code is tailored to the requirements of operational weather forecasting for the aviation community and for public weather forecasting. As such, the emphasis is on computing efficiency, performance verification, simplicity of design (for rapid problem resolution), and regional tailorability. Results from preliminary testing are presented. A variety of procedures illustrate model attributes such as water mass conservation and physical realism, and some of the algorithm's limitations. THE SEA BREEZE CONVERGENCE ZONE AND ITS RELATIONSHIP TO FAIR WEATHER ELECTRICITY IN EAST CENTRAL FLORIDA M.S. Thesis
Sabrina Taijeron 1993 113 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A268511; AFIT/CI/CIA-93-121) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research focused on the relationship between the fair weather electric field and the sea breeze convergence zone at the KSC/CCAFS. Wind sensor and electric field mill data from the CaPE project were analyzed. This study did not reveal any clear indication of a higher electric field during sea breeze convergence. The two phenomena exist, but their interactions appear to be weak. The expected interaction might be found in bigger data sets or through other types of analysis. DTIC

NEXT GENERATION WEATHER RADAR (NEXRAD) PRINCIPAL USER PROCESSOR (PUP) OPERATIONAL TEST AND EVALUATION (OT/E) Operational Report
Baxter Stretcher Oct. 1993 38 p
(AD-A273075; DOT/FAA/CT-TN93/36) Avail: CASI HC A03/MF A01

This report details the results of the Operational Test and Evaluation (OT&E) Operational Test of the Next Generation Weather Radar (NEXRAD), Principle User Processor (PUP). The PUP was evaluated at the Leesburg, Virginia, and Houston, Texas, Air Route Traffic Control Centers (ARTCC) during the period 22 Mar. through 1 Apr. 1993. The objective of the OT&E Operational Test was to obtain the Central Weather Service Unit (CWSU) meteorologists' evaluation of the NEXRAD PUP. A questionnaire was used to obtain responses from the meteorologists. This report includes the meteorologists' evaluation of the quality and quantity of the products provided by the PUP, the workload, operational procedures, radar connections, and training. DTIC

A SYNOPTIC-SCALE OVERVIEW OF THE TOGA COARE INTENSIVE OBSERVING PERIOD NOVEMBER 1992 TO FEBRUARY 1993 BASED ON ANALYSES FROM US OPERATIONAL GLOBAL DATA ASSIMILATION SYSTEMS
M. Fiorino (Universities Space Research Association, Columbia, MD.), S. J. Lord (National Meteorological Center, Camp Springs, MD.), W. K.-M. Lau, P. A. Phoebus (Naval Research Lab., Monterey, CA.), and C. G. Strey (Fleet Numerical Oceanography Center, Monterey, CA.) Nov. 1993 270 p
(NASA-TM-104593; Rept-94B00015; NAS 1.15:104593) Avail: CASI HC A12/MF A03

The operational global analyses from the two major U.S. numerical weather prediction centers, the Navy's Fleet Numerical Oceanography Center and the National Meteorological Center, are used to describe the synoptic-scale features of the 1 Nov. 1992 to 28 Feb. 1993 TOGA COARE intensive observing period (IOP). TOGA COARE is an international field experiment in which a large number of research scientists from the Goddard Laboratory for Atmospheres (Code 910) and the Laboratory for Hydrospheres (Code 970) participated. Two high-amplitude intraseasonal (30-60 day) oscillations passed through the TOGA COARE observational network located in the equatorial western Pacific. Associated with the oscillations were two 6-10 day periods of persistent westerly surface winds at the equator or 'westerly wind bursts.' These events are depicted through time series and time-longitude cross sections of divergence/velocity potential, surface winds, precipitation, ocean mixed-layer depth, and sea surface temperature. The high and low frequency components of the flow in which the intraseasonal oscillations were embedded are shown using seasonal, monthly, and 5-day averages of the surface, 850 and 200 mb winds, precipitation, and sea-level pressure, and a time-longitude cross section of tropical cyclone activity. Independent verification of precipitation comes from near real-time satellite estimates, and a reference climatology is given based on 9 years of ECMWF analyses. Daily 00 UTC analyses of surface winds and sea-level pressure for the entire western Pacific and Indian Ocean are provided to trace the evolution of individual synoptic events. Author (revised)

A workshop on Long-Term Monitoring of Global Climate Forcings and Feedbacks was held February 3-4, 1992, at NASA's Goddard Institute for Space Studies to discuss the measurements required to interpret long-term global temperature changes, to critique the proposed contributions of a series of small satellites (Climsat), and to identify needed complementary monitoring. The workshop concluded that long-term (several decades) of continuous monitoring of the major climate forcings and feedbacks is essential for understanding long-term climate change. For individual titles, see N94-21640 through N94-21648.

Recognition that earth's climate and biogeophysical conditions are likely changing due to human activities has led to a heightened awareness

of the need for improved long-term global monitoring. The present long-term measurement efforts tend to be spotty in space, inadequately calibrated in time, and internally inconsistent with respect to other instruments and measured quantities. In some cases, such as most of the biosphere, most chemicals, and much of the ocean, even a minimal monitoring program is not available. Recently, it has become painfully evident that emerging global change issues demand information and insights that the present global monitoring system simply cannot supply. This is because a monitoring system must provide much more than a statement of change at a given level of statistical confidence. It must describe changes in diverse parts of the entire earth system on regional to global scales. It must be able to provide enough input to allow an integrated physical characterization of the changes that have occurred. Finally, it must allow a separation of the observed changes into their natural and anthropogenic parts. The enormous policy significance of global change virtually guarantees an unprecedented level of scrutiny of the changes in the earth system and why they are happening. These pressures create a number of emerging challenges and opportunities. For example, they will require a growing partnership between the observational programs and the theory/modeling community. Without this partnership, the scientific community will likely fall short in the monitoring effort. The monitoring challenge before us is not to solve the problem now, but rather to set appropriate actions in motion so as to create the required framework for solution. Each individual piece needs to establish its role in the large problem and how the required interactions are to take place. Below, we emphasize some of the needs and opportunities that could and should be addressed through participation by the theoreticians and modelers in the global change monitoring effort. CLIMATE FORCINGS AND FEEDBACKS

James Hansen *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 6-12 (For primary document see N94-21639 05-47)

Avail: CASI HC A02/MF A02; 13 functional color pages

Global temperature has increased significantly during the past century. Understanding the causes of observed global temperature change is impossible in the absence of adequate monitoring of changes in global climate forcings and radiative feedbacks. Climate forcings are changes imposed on the planet's energy balance, such as change of incoming sunlight or a human-induced change of surface properties due to deforestation. Radiative feedbacks are radiative changes induced by climate change, such as alteration of cloud properties or the extent of sea ice. Monitoring of global climate forcings and feedbacks, if sufficiently precise and long-term, can provide a very strong constraint on interpretation of observed temperature change. Such monitoring is essential to eliminate uncertainties about the relative importance of various climate change mechanisms including tropospheric sulfate aerosols from burning of coal and oil smoke from slash and burn agriculture, changes of solar irradiance changes of several greenhouse gases, and many other mechanisms. The considerable variability of observed temperature, together with evidence that a substantial portion of this variability is unforced indicates that observations of climate forcings and feedbacks must be continued for decades. Since the climate system responds to the time integral of the forcing, a further requirement is that the observations be carried out continuously. However, precise observations of forcings and feedbacks will also be able to provide valuable conclusions on shorter time scales. For example, knowledge of the climate forcing by increasing CFC's relative to the forcing by changing ozone is important to policymakers, as is information on the forcing by CO2 relative to the forcing by sulfate aerosols. It will also be possible to obtain valuable tests of climate models on short time scales, if there is precise monitoring of all forcings and feedbacks during and after events such as a large volcanic eruption or an El Nino.

ACCURACY REQUIREMENTS

Anthony DelGenio *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 13-19 (For primary document see N94-21639 05-47)

Avail: CASI HC A02/MF A02; 13 functional color pages

Satellite and surface measurements, if they are to serve as a climate monitoring system, must be accurate enough to permit detection of changes of climate parameters on decadal time scales. The accuracy requirements are difficult to define a priori since they depend on unknown future changes of climate forcings and feedbacks. As a framework for evaluation of candidate Climsat instruments and orbits, we estimate the accuracies that would be needed to measure changes expected over two decades based on theoretical considerations including GCM simulations and on observational evidence in cases where data are available for rates of change. One major climate forcing known with reasonable accuracy is that caused by the anthropogenic homogeneously mixed greenhouse gases (CO2, CFC's, CH4 and N2O). Their net forcing since the industrial revolution began is about 2 W/sq m and it is presently increasing at a rate of about 1 W/sq m per 20 years. Thus for a competing forcing or feedback to be important, it needs to be of the order of 0.25 W/sq m or larger on this time scale. The significance of most climate feedbacks depends on their sensitivity to temperature change. Therefore we begin with an estimate of decadal temperature change. Presented are the transient temperature trends simulated by the GISS GCM when subjected to various scenarios of trace gas concentration increases. Scenario B, which represents the most plausible near-term emission rates and includes intermittent forcing by volcanic aerosols, yields a global mean surface air temperature increase Delta Ts = 0.7 degrees C over the time period 1995-2015. This is consistent with the IPCC projection of about 0.3 degrees C/decade global warming (IPCC, 1990). Several of our estimates below are based on this assumed rate of warming. Derived from text

CLIMSAT RATIONALE

James Hansen *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 26-35 (For primary document see N94-21639 05-47)

Avail: CASI HC A02/MF A02; 13 functional color pages

We summarize reasons for the Climsat proposition; we also stress the need for certain climate monitoring other than that supplied by Climsat, especially solar irradiance, and we stress the complementarity of Climsat monitoring to plans for detailed EOS measurements. Existing and planned observations will not provide measurements of most climate forcing and feedback parameters with the accuracy needed to measure plausible decadal changes. Stratospheric water vapor and aerosol requirements are not met, for example, even though the present SAGE II instrument on the ERBS spacecraft measures those two parameters accurately, because ERBS is not expected to last more than a few years and it does not provide global coverage. We stress the imminence of a potential data gap even of those parameters, such as solar irradiance and stratospheric aerosols, for which monitoring capability has been proven and currently is in place. We find that most of the missing global climate forcings and feedbacks can be measured by three small instruments, which would need to be deployed on two spacecraft to obtain adequate sampling and global coverage. The monitoring must be maintained continuously for at least two decades. Such continuity can be attained by replacing a satellite after it fails, the functioning satellite providing calibration transfer to the new satellite. Certain complementary monitoring data are also needed, including solar monitoring from space, in order to fully meet requirements for monitoring all the climate forcings and feedbacks. The complementary data needs are discussed toward the end of this section. We summarize the proposed Climsat measurements and compare the expected accuracies to those which are needed to analyze changes of the global thermal energy cycle on decadal time scales. We stress the need to get broader participation of the scientific community in the monitoring and analysis activity. Finally, we discuss related climate process and diagnostic measurements.

STRATOSPHERIC AEROSOL AND GAS EXPERIMENT (SAGE 3)

M. P. McCormick *In* NASA. Goddard Inst. for Space Studies, Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 36-39 (For primary document see N94-21639 05-47)

Avail: CASI HC A01/MF A02; 13 functional color pages

The proposed SAGE III instrument would be the principal source of

data for global changes of stratospheric aerosols, stratospheric water vapor, and ozone profiles, and a contributing source of data for upper tropospheric water vapor, aerosols, and clouds. The ability to obtain such data has been demonstrated by the predecessor instrument, SAGE II, but SAGE III will be substantially more capable, as discussed below. The capabilities for monitoring the profiles of atmospheric constituents have been verified in detail, including ground-based validations, for aerosol, ozone, and water vapor. Indeed, because of its self-calibrating characteristics, SAGE II was an essential component of the international ozone trend assessments, and SAGE II is now proving to be invaluable in tracking the aerosols from Mt. Pinatubo. Although SAGE profiles generally terminate at the height of the first tropospheric cloud layer, it has been found that the measurements extend down to 3 km altitude more than 40 percent of the time at most latitudes. Thus, useful information can also be obtained on upper tropospheric aerosols, water vapor, and ozone. Derived from text

EARTH OBSERVING SCANNING POLARIMETER **c43**

Larry Travis *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 40-46 (For primary document see N94-21639 05-47)

Avail: CASI HC A02/MF A02; 13 functional color pages

Climate forcing by tropospheric aerosols is receiving increased attention because of the realization that the climate effects may be large, while our knowledge of global aerosol characteristics and temporal changes is very poor. Tropospheric aerosols cause a direct radiative forcing due simply to their scattering and absorption of solar radiation, as well as an indirect effect as cloud condensation nuclei which can modify the shortwave reflectivity of clouds. Sulfate aerosols tend to increase planetary albedo through both the direct and indirect effects; a cooling due to anthropogenic sulfate aerosols has been estimated of order 1 W/sq m, noting that this is similar in magnitude to the present anthropogenic greenhouse gas warming. Other aerosols, including those from biomass burning and wind-blown desert dust are also of potential climatic importance. At present, the only global monitoring of tropospheric aerosols is a NOAA operational product, aerosol optical thickness, obtained using channel-1 (0.58-0.68 mu m) radiances from the AVHRR. With this single channel radiance data, one must use an approach which is based on the inferred excess of reflected radiance owing to scattering by the aerosols over that expected from theoretical calculations. This approach is suited only for situations where the surface has a low albedo that is well known a priori. Thus, the NOAA operational product is restricted to coverage over the ocean at AVHRR scan angles well away from sun glint, and aerosol changes are subject to confusion with changes caused by either optically thin or subpixel clouds. Because optically thin aerosols have only a small effect on the radiance, accurate measurements for optical thickness less than 0.1 (which is a typical background level) are precluded. Moreover, some of the largest and most important aerosol changes are expected over land. The Earth Observing Scanning Polarimeter (EOSP) instrument, based upon design heritage and analysis techniques developed for planetary missions, will retrieve tropospheric aerosol characteristics from measurements of multispectral radiance and polarization. Moreover, the same radiance and polarization measurements will also provide very precise information on cloud properties and maps of surface characteristics for cloud-free regions. These capabilities also give EOSP the unique ability to discriminate aerosol from clouds and surface. Derived from text

MICHELSON INTERFEROMETER (MINT) **c35**

Andrew Lacis and Barbara Carlson *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 47-53 (For primary document see N94-21639 05-47)

Avail: CASI HC A02/MF A02; 13 functional color pages

MINT is a Michelson interferometer designed to measure the thermal emission from the earth at high spectral resolution (2/cm) over a broad spectral range (250-1700/cm, 6-40 mu m) with contiguous 3-pixel wide (12 mrad, 8 km field of view) along-track sampling. MINT is particularly well suited for monitoring cloud properties (cloud cover, effective temperature, optical thickness, ice/water phase, and effective particle size) both day and night, as well as tropospheric water vapor, ozone, and temperature. The key instrument characteristics that make MINT ideally suited for decadal monitoring purposes are: high wavelength to wavelength precision across the full IR spectrum with high spectral resolution; space-proven long-term durability and calibration stability; and small size, low cost, low risk instrument incorporating the latest detector and electronics technology. MINT also incorporates simplicity in design and operation by utilizing passively cooled DTGS detectors and nadir viewing geometry (with target motion compensation). MINT measurement objectives, instrument characteristics, and key advantages are summarized in this paper. Derived from text

ORBIT AND SAMPLING REQUIREMENTS: TRMM EXPERIENCE

Gerald North *In* NASA. Goddard Inst. for Space Studies, Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 54-56 (For primary document see N94-21639 05-47)

Avail: CASI HC A01/MF A02; 13 functional color pages

The Tropical Rainfall Measuring Mission (TRMM) concept originated in 1984. Its overall goal is to produce datasets that can be used in the improvement of general circulation models. A primary objective is a multi-year data stream of monthly averages of rain rate over 500 km boxes over the tropical oceans. Vertical distributions of the hydrometers, related to latent heat profiles, and the diurnal cycle of rainrates are secondary products believed to be accessible. The mission is sponsored jointly by the U.S. and Japan. TRMM is an approved mission with launch set for 1997. There are many retrieval and ground truth issues still being studied for TRMM, but here we concentrate on sampling since it is the single largest term in the error budget. The TRMM orbit plane is inclined by 35 degrees to the equator, which leads to a precession of the visits to a given grid box through the local hours of the day, requiring three to six weeks to complete the diurnal cycle, depending on latitude. For sampling studies we can consider the swath width to be about 700 km. Derived from text

SATELLITE ORBIT AND DATA SAMPLING REQUIREMENTS

William Rossow *In its* Long-Term Monitoring of Global Climate Forcings and Feedbacks Sep. 1993 p 57-67 (For primary document see N94-21639 05-47)

Avail: CASI HC A03/MF A02; 13 functional color pages

Climate forcings and feedbacks vary over a wide range of time and space scales. The operation of non-linear feedbacks can couple variations at widely separated time and space scales and cause climatological phenomena to be intermittent. Consequently, monitoring of global, decadal changes in climate requires global observations that cover the whole range of space-time scales and are continuous over several decades. The sampling of smaller space-time scales must have sufficient statistical accuracy to measure the small changes in the forcings and feedbacks anticipated in the next few decades, while continuity of measurements is crucial for unambiguous interpretation of climate change. Shorter records of monthly and regional (500-1000 km) measurements with similar accuracies can also provide valuable information about climate processes, when 'natural experiments' such as large volcanic eruptions or El Ninos occur. In this section existing satellite datasets and climate model simulations are used to test the satellite orbits and sampling required to achieve accurate measurements of changes in forcings and feedbacks at monthly frequency and 1000 km (regional) scale. Fraser (Canterbury Univ., Christchurch, New Zealand.), T. Tsuda (Kyoto Univ., Japan.), and F. Vial (Ecole Polytechnique, Palaiseau, France.) et al Washington Nov. 1993 101 p

(NASA-TM-104592; NAS 1.15:104592; Rept-94B00005) Avail: CASI HC A06/MF A02

The HWM90 thermospheric wind model was revised in the lower

thermosphere and extended into the mesosphere and lower atmosphere to provide a single analytic model for calculating zonal and meridional wind profiles representative of the climatological average for various geophysical conditions. Local time variations in the mesosphere are derived from rocket soundings, incoherent scatter radar, MF radar, and meteor radar. Low-order spherical harmonics and Fourier series are used to describe these variations as a function of latitude and day of year with cubic spline interpolation in altitude. The model represents a smoothed compromise between the original data sources. Although agreement between various data sources is generally good, some systematic differences are noted. Overall root mean square differences between measured and model tidal components are on the order of 5 to 10 m/s. Author (revised)

The results of 22 further horizontal soundings were arranged according to their synoptic conditions. Among the results were the following: in clouds of a high pressure area, on flight paths between 40 and 75 km and when the distance from the cloud base was constant, the total water content (TWC) fluctuated between approximately equal to 0.10 and approximately equal to 0.18 g/cu m and between approximately equal to 0.10 and approximately 0.25 g/cu m respectively. The value for the median volume diameter (MVD) was always small, between 8 and 20 micrometers. In the vicinity of cold and warm fronts or in flow from different directions, the value of TWC fluctuated between 0 and 0.10 g/cu m up to between 0 and 0.55 g/cu m on flight distances between 35 and 145 km. The value of MVD had small or large values on flight distances of different length or fluctuated between small values (8 to 50 micrometers) and larger values (up to 600 micrometers). ESA

CIRRUS MICROPHYSICS OBSERVATIONS MADE DURING FIRE 2: SMALL PARTICLES, HIGH CONCENTRATIONS, AND PROBE COMPARISONS

W. P. Arnott, Y. Y. Dong, J. Hallett, and M. R. Poellot (North Dakota Univ., Grand Forks.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 5-8 (For primary document see N94-22292 05-47)

(Grant NAG1-1113)

Avail: CASI HC A01/MF A03

Aircraft observations of cirrus cloud microphysics were made near Coffeyville, Kansas during Nov. and Dec. 1991. Cloud microphysics measurements were made using both a PMS 2DC probe and an ice particle replicator, both were mounted on the UND Citation aircraft. Intercomparison is made of the size, area, and ice mass spectra determined from these probes. The PMS 2DC undercounts particles for D less than 70 microns and the replicator oversizes particles for D greater than 150 microns, at least when column rosettes are encountered. High concentrations of particles with D less than 50 microns are noted in selected portions of the 22 Nov. 91 replicator data set. Relations between the maximum dimension of a crystal and its shadow area (known as area dimensional relationships) are computed from the PMS data. Area and mass dimensional relationships are used to give a simple analytical expression for computing the wavelength dependent absorption coefficient averaged over a size bin. Calculations based upon the replicator data show that crystals with D less than 50 microns contribute significantly to the solar extinction and infrared absorption coefficients during some time intervals. CIRRUS PROPERTIES DEDUCED FROM CO2 LIDAR OBSERVATIONS OF ZENITH-ENHANCED BACKSCATTER FROM ORIENTED CRYSTALS 00

Wynn L. Eberhard *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 9-12 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

Many lidar researchers have occasionally observed zenith-enhanced backscatter (ZEB) from middle and high clouds. The ZEB signature consists of strong backscatter when the lidar is pointed directly at zenith and a dramatic decline in backscatter as the zenith angle dips slightly off zenith. Mirror-like reflection from horizontal facets of oriented crystals (especially plates) is generally accepted as the cause. It was found during a 3-year observation program that approximately 50 percent of ice clouds had ZEB, regardless of cloud height. The orientation of crystals and the ZEB they cause are important to study and understand for several reasons. First, radiative transfer in clouds with oriented crystals is different than if the same particles were randomly oriented. Second, crystal growth depends partly on the orientation of the particles. Third, ZEB measurements may provide useful information about cirrus microphysical and radiative properties. Finally, the remarkable effect of ZEB on lidar signals should be understood in order to properly interpret lidar data. Author (revised)

BI-DIRECTIONAL REFLECTANCE AND OTHER RADIATION PARAMETERS OF CIRRUS FROM ER-2 OBSERVATIONS

James Spinhime *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 13-16 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

Passive and active remote sensing of cirrus were acquired from the ER-2 high altitude aircraft in the 1991 Cirrus Experiment. The observations include direct measurements of cirrus bi-directional reflectance from a new translinear scanning radiometer and the previously employed measurements

by lidar and visible-infrared imaging radiometers. For any cirrus radiative transfer application, it is necessary to know the appropriate model for visible reflectance in relation to angle and also the optical thickness and infrared emissivity of the clouds. At a more complicated level, for remote sensing and overall cloud effects it is ultimately required to understand effects from multiple cloud layers, broken clouds, and variable microphysics. Our overall data set from the scanning radiometers and lidar is intended to provide the necessary observations to investigate these problems.

OPTICAL PROPERTIES OF CIRRUS DERIVED FROM AIRBORNE MEASUREMENTS DURING FIRE IFO 2
Francisco P. J. Valero, Peter Pilewskie, Anthony Bucholtz, and Steven Platnick *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 17-19 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

The Radiation Measurement System (RAMS) on board the NASA ER-2 was used to acquire several optical parameters of interest during the FIRE Cirrus IFO 2. In this abstract we present results from the 26 Nov. IFO when the ER-2 flew over the Coffeyville airport hub site. We show retrieved optical thickness and cloud temperature, along with optical thickness obtained from RAMS instruments on the NCAR Sabreliner and at the surface site B. Independent retrieval of optical thickness, from the ER-2 and at the surface, are in agreement during the overpasses. Cirrus optical depths, derived from each platform, ranged between 1 and 2.

INTERCOMPARISON OF MAS, AVIRIS, AND HIS DATA FROM FIRE CIRRUS 2
Liam E. Gumley (Research and Data Systems, Inc., Greenbelt, MD.), Michael D. King, Si-Chee Tsay, Bo-Cai Gao, and G. Thomas Arnold (Applied Research Corp., Landover, MD.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 20-23 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

The NASA ER-2 flight on 5 Dec. 1991 is unique among the FIRE Cirrus 2 missions in that data were acquired simultaneously by the MODIS Airborne Simulator (MAS), the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS), and the High Resolution Interferometer Sounder (HIS). These data represent a unique source of information about the spatial and spectral properties of cirrus clouds. The MAS is a new instrument which will aid in defining algorithms and building an understanding of the ability of the Moderate Resolution Imaging Spectroradiometer (MODIS) to remotely sense atmospheric conditions for assessing global change. In order to establish confidence in the absolute calibration accuracy of the MAS radiances, an inter-comparison of MAS radiances with AVIRIS and HIS has been undertaken.

Meteorological satellite instrument pixel sizes are often much greater than the individual cloud elements in a given scene. Partially cloud-filled pixels can be misinterpreted in many analysis schemes because the techniques usually assume that all of the cloudy pixels are cloud filled. Coincident Landsat and Geostationary Operational Environmental Satellite (GOES) data and degraded-resolution Landsat data were used to study the effects of both sensor resolution and analysis techniques on satellite-derived cloud parameters. While extremely valuable for advancing the understanding of these effects, these previous studies were relatively limited in the number of cloud conditions that were observed and by the limited viewing and illumination conditions. During the First ISCCP Regional Experiment (FIRE) Phase 2 (13 Nov. - 7 Dec. 1991), the NASA ER-2 made several flights over a wide range of cloud fields and backgrounds with several high resolution sensors useful for a variety of purposes including serving as ground truth for satellite-based cloud retrievals. This paper takes a first look at utilizing the ER-2 for validating cloud parameters derived from GOES and NOAA-11 Advanced Very High Resolution Radiometer (AVHRR) data.

CLOUD PROPERTIES FROM THE ANALYSIS OF AVHRR OBSERVATIONS FOR FIRE 2
Xijian Lin and James A. Coakley, Jr. *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 28-31 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

Preliminary results are presented for cloud properties from the analysis of AVHRR observations for FIRE 2. The properties were obtained from a combination of the spatial coherence method and a multispectral retrieval scheme. Geographically gritted fields for the number of cloud layers were produced. For single layered cloud systems, fractional cloud cover, cloud emission temperature, cloud emissivity, and particle size were retrieved. Statistics on the properties of upper-level clouds and the Coffeeville cloud conditions are presented.

Avail: CASI HC A01/MF A03

Cloud-top height is a major factor determining the outgoing longwave flux at the top of the atmosphere. The downwelling radiation from the cloud strongly affects the cooling rate within the atmosphere and the longwave radiation incident at the surface. Thus, determination of cloud-base temperature is important for proper calculation of fluxes below the cloud. Cloud-base altitude is also an important factor in aircraft operations. Cloud-top height or temperature can be derived in a straightforward manner using satellite-based infrared data. Cloud-base temperature, however, is not observable from the satellite, but is related to the height, phase, and optical depth of the cloud in addition to other variables. This study uses surface and satellite data taken during the First ISCCP Regional Experiment (FIRE) Phase-2 Intensive Field Observation (IFO) period (13 Nov. - 7 Dec. 1991, to improve techniques for deriving cloud-base height from conventional satellite data.

The interpretation of surface and aircraft measurements of cloud properties taken during field programs must take into account the large-scale cloud and meteorological conditions. Cloud properties are also required at

scales beyond the point and line data taken from ground and aircraft platforms. Satellite data can provide a quantitative description of these large-scale cloud properties. When derived from geostationary satellite data, the cloud fields constitute a unique source for evaluating the development and demise of a cloud system. Satellites, however, can only see the tops of clouds, so that cloud layers below the uppermost cloud deck may remain undetected resulting in a incomplete depiction of the cloud system. Some multilayer clouds are amenable to detection from satellites. Many, especially in midlatitude cyclonic systems, can only be observed from the surface. A combination of surface and satellite cloud observations should be the most complete quantification of large-scale cloudiness if there are sufficient surface measurements. During the First International Satellite Cloud Climatology Project (ISCCP) Regional Experiment Phase 2 (FIRE-2) Cirrus Intensive Field Observation (IFO) period (November 13 - December 7, 1991) conducted at Coffeyville, Kansas, cirrus observations were taken in a variety of conditions. The IFO area was selected for a variety of reasons including the relatively dense network of surface weather stations and special surface instrumentation sites. Thus, the FIRE-2 IFO presents an excellent opportunity to combine cloud observations from surface and satellite observations. This paper presents an analysis of cloud properties on a mesoscale grid using satellite cloud property retrievals, surface observer data, and rawinsonde temperature and humidity profiles.

REMOTE SENSING OF MULTILEVEL CLOUDS DURING FIRE IFO 2 c43

Bryan A. Baum, J. Titlow (Lockheed Engineering and Sciences Co., Hampton, VA.), V. Tovinkere (Lockheed Engineering and Sciences Co., Hampton, VA.), M. Poellot (North Dakota Univ., Grand Forks.), T. P. Ackerman (Pennsylvania State Univ., University Park.), J. Alvarez, T. Uttal (National Oceanic and Atmospheric Administration, Boulder, CO.), and J. Intrieri (Colorado Univ., Boulder.) *In its* The FIRE Cirrus Science Results 1993 Dec. 1993 p 40-43 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

An unresolved difficulty in the remote sensing of clouds concerns the inability of the cloud retrieval algorithms to adequately recognize and analyze scenes containing overlapping cloud layers. Most cloud retrieval schemes, such as that used by the International Satellite Cloud Climatology Project (ISCCP) assume that each picture element (pixel) contains a single cloud layer. The current study begins to address the complexities of multilayered cloud property retrieval through the application of a modified multispectral, multiresolution (MSMR) method, first detailed in Baum et al. (1992), which merges 1.1 -km (at nadir) spectral data from the Advanced Very High Resolution Radiometer (AVHRR) with 17.4-km (at nadir) High Resolution Infrared Radiometer Sounder (HIRS/2, henceforth HIRS). Both instruments are flown aboard the National Oceanic and Atmospheric Administration (NOAA) polar-orbiting platforms. An ideal case study for this investigation is provided by the NOAA-11 overpass at 20:48 UTC on November 28, 1991. At this time, a large-scale cirrostratus veil overlaid a low-level stratus deck over much of the IFO region. There were both surface lidar and radar observations of the clouds as well as University of North Dakota (UND) Citation aircraft measurements. The presence of overlapping cloud layers within a HIRS FOV is determined from colocated AVHRR spectral data through the use of a fuzzy logic expert system. Conventional algorithms such as spatial coherence and CO2 slicing are used to retrieve cloud pressure and height for each identified cloud layer. The results from the satellite cloud retrieval analysis are compared to results from both surface- and aircraft-based measurements. Derived from text

MICROPHYSICAL PROPERTIES OF THE NOVEMBER 26 CIRRUS CLOUD RETRIEVED BY DOPPLER RADAR/IR RADIOMETER TECHNIQUE

Sergey Y. Matrosov, Robert A. Kropfli (National Oceanic and Atmospheric Administration, Boulder, CO.), Brad W. Orr (National Oceanic and Atmospheric Administration, Boulder, CO.), and Jack B. Snider (National Oceanic and Atmospheric Administration, Boulder, CO.) *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 44-47 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

Gaining information about cirrus cloud microphysics requires development of remote sensing techniques. In an earlier paper. Matrosov et al. (1992) proposed a method to estimate ice water path (IWP) (i.e., vertically integrated ice mass content IMC) and characteristic particle size averaged through the cloud from combined groundbased measurements of radar reflectivities and IR brightness temperatures of the downwelling thermal radiation in the transparency region of 10-12 mu m. For some applications, the vertically averaged characteristic particle sizes and IWP could be the appropriate information to use. However, vertical profiles of cloud microphysical parameters can provide a better understanding of cloud structure and development. Here we describe a further development of the previous method by Matrosov et al. (1992) for retrieving vertical profiles of cirrus particle sizes and IMC rather than their vertically averaged values. In addition to measurements of radar reflectivities, the measurements of Doppler velocities are used in the new method. This provides us with two vertical profiles of measurements to infer two vertical profiles of unknowns, i.e., particle characteristic sizes and IMC. Simultaneous measurements of the IR brightness temperatures are still needed to resolve an ambiguity in particle size-fall velocity relationships. Derived from text

LIDAR AND RADAR DERIVED CIRRUS MICROPHYSICAL PROPERTIES FOR THE 26 NOVEMBER 1991 CASE STUDY

Janet M. Intrieri and Graham Feingold *In* NASA. Langley Research Center, The FIRE Cirrus Science Results 1993 Dec. 1993 p 48-51 (For primary document see N94-22292 05-47)

Avail: CASI HC A01/MF A03

The Wave Propagation Laboratory's CO2 lidar (lambda = 10.6 microns) and Ka-band radar (lambda = 8.66 mm) operate at widely separated wavelengths; the differences in how the transmitted waves interact with cloud targets can be exploited to provide information that neither sensor could provide alone. This can be as simple as overlapping the data sets to provide additional coverage on cloud geometry (see Uttal and Intrieri, 1993) or combining the measurements in a theoretical framework to provide cirrus cloud parameters of the size spectrum, i.e., characteristic particle size and number concentration. In this paper, the latter option is described and an example case study presented to illustrate the types of information available for cloud and radiation transfer models. Derived from text

Avail: CASI HC A01/MF A03

Cloud microphysical properties are an important component in climate model parameterizations of water transport, cloud radiative exchange, and latent heat processes. Estimation of effective cloud particle size, liquid or ice water content, and optical depth from satellite-based instrumentation is needed to develop a climatology of cloud microphysical properties and to better understand and model cloud processes in atmospheric circulation. These parameters are estimated from two different surface data sets taken at Coffeyville, Kansas, during the First ISCCP Regional Experiment (FIRE) Phase-2 Intensive Field Observation (IFO) period (November 13 - December 7, 1991). Satellite data can also provide information about optical depth and effective particle size. This paper explores the combination of the FIRE-2 surface and satellite data to determine each of the cloud microphysical properties. Derived from text

A NUMERICAL TECHNIQUE FOR THE CALCULATION OF CLOUD OPTICAL EXTINCTION FROM LIDAR
J. M. Alvarez and M. A. Vaughan (Science Applications International Corp., Hampton, VA.) *In its* The FIRE Cirrus Science Results 1993 Dec. 1993 p 67-70 (For primary document see N94-22292 05-47)
Avail: CASI HC A01/MF A03

A simple numerical algorithm which calculates optical extinction from cloud lidar data is presented. The method assumes a two-component atmosphere consisting of 'clear air' and cloud particulates. 'Clear air' may consist of either molecules only or a mix of molecules and atmospheric aerosols. For certain clouds, the method may be utilized to provide an estimate of the cloud-atmospheric parameter defined as the ratio of the cloud volume backscatter coefficient to the cloud extinction coefficient divided by the atmospheric volume backscatter coefficient at a given altitude. The cloud-atmospheric parameter may be estimated only from cloud data from which the optical thickness may reliably be used as a constraint on the numerical solution. This constraint provides the additional information necessary to obtain the cloud-atmospheric parameter. Conversely, the method may be applied to obtain cloud extinction and optical thickness from lidar cloud soundings if an estimate of the cloud-atmospheric parameter is available. Author (revised)
